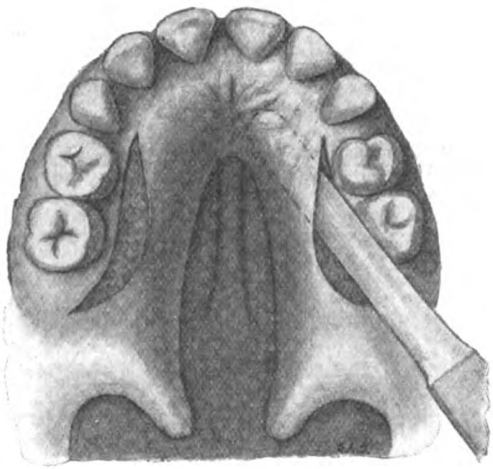
Sutures, &c.—In order to be quite sure that the edges of the wound are everted and raw surfaces brought together I use one or two button sutures (Fig. 5). For suture material I use silver wire and fine silkworm gut. In exceptional cases I have surrounded the flaps with tape impregnated with Horsley's wax (Fig. 6), and am satisfied it served a useful purpose. This use of tape was suggested some five years ago by Dr. Charles Mayo, of Rochester, but it is well to remember that the same idea occurred to Mr. Pollock, of St. George's Hospital, in 1863, and that he also discussed the advisability of plugging the lateral incisions with gauze. The operation completed, I have frequently, but not invariably, washed out the stomach, a tube being passed into the stomach through the nostril. It is certainly satisfactory to get away a quantity of blood and mucus which has been swallowed.

After-treatment.—This is almost entirely a question of nursing, the chief points being to keep the mouth clean and to maintain the child's general health. If on recovering from the anæsthetic the child should cry and not be pacified, a few minims of nepenthe may be given. In children over 4 years of age nasal feeding may with advantage be used during the week following the operation, but in younger children it is impracticable. In ordinary mouth feeding milk should not be given, for it clings to the stitches, is difficult to wash away, and undergoes fermentation changes. Valentine's meat juice, soups, or bovril are much to be preferred. Half an hour after each feeding the palate should be cleansed by syringing with warm water. If the child will not permit this, a drink of water must be given at the conclusion of each meal. If the bowels are not opened on the day following the operation a dose of castor oil must be given.



Surgeons are greatly handicapped by having to keep their patients after operation confined in the more or less impure atmosphere of a children's ward in a city hospital. It is a pity our children's hospitals are not out of town. I am sure all cases would do better, and I am convinced of this—that the results of cleft palate operations would be much more satisfactory than they are at present if after the operation the children could breathe fresh country air.

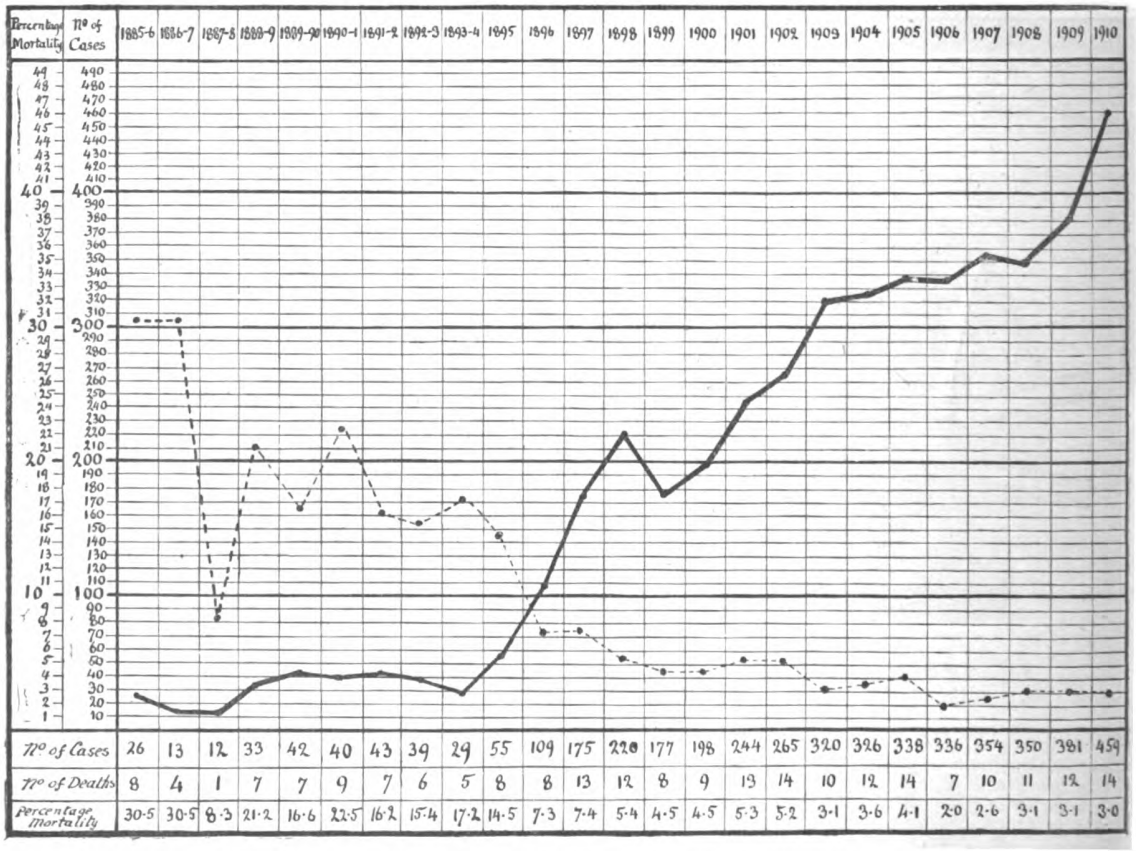
Waxed tape encircling both flaps to relieve tension on the suture line (very rarely necessary).

THE EVOLUTION OF MODERN GYNÆCOLOGY.*

BY ARTHUR E. GILES, M.D., B.SC. LOND., F.R C.S. EDIN.,
SURGEON TO THE CHELSEA HOSPITAL FOR WOMEN; GYNÆCOLOGIST TO THE PRINCE OF WALES'S GENERAL HOSPITAL, TOTTENHAM, N.

WHEN I was asked to deliver this address I fell naturally to thinking of the contrast between the gynæcology of my student days and that of the present time. Exactly 25 years have passed since I began to attend a course of lectures on obstetrics and gynæcology, given at Owens College by my revered teacher and honoured friend, the late Dr. C. J. Cullingworth. As a lecturer he had few equals, and to the interest that he inspired I ascribe my subsequent decision to work in the same department of medicine as that wherein he laboured. But even his lucidity and enthusiasm could not entirely clear away the vague and nebulous atmosphere that surrounded much of the teaching of the diseases of women 25 years ago. It will be a pleasurable duty to show that he played no small part in helping to dissipate the mists and display the province of gynæcology in a fair and comprehensive perspective.



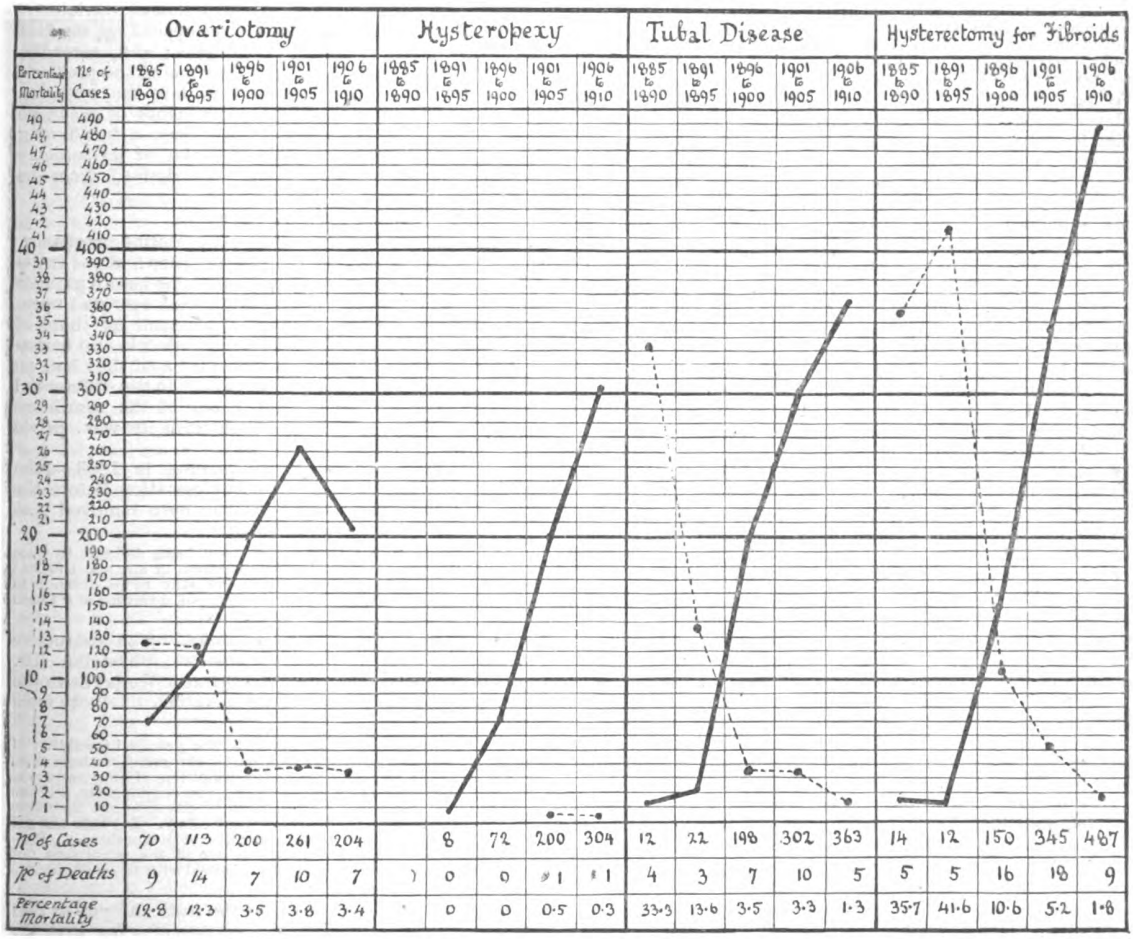
I take, then, as my subject, "The Evolution of Modern Gynæcology." It is no part of my idea to endeavour to trace the development of gynæcology in the dark ages or in the far-off past—those interested in such matters may refer to the learned work of Stewart McKay on "The History of Ancient Gynæcology." I will only call attention to a curious illustration, cited in this work, of the proverb that nothing is new under the sun. We are accustomed to think that ovariotomy was a product of the nineteenth century, but Stewart McKay [1] refers to the statement of Athenaeus, in his "Denosophists," that Xanthus relates that "Adramyttes, the King of the Lydians, was the first man who ever castrated women, and used female eunuchs instead of male eunuchs."

The evolution that I should like to speak of is that which has taken place in the last 25 years; but the origins of some of its phases must be sought in an earlier period in order to be understood, and therefore I shall have to refer to certain events that date back from 50 to 100 years.

By way of text I shall call your attention to the two accompanying charts. Chart I. shows the number of abdominal operations of all kinds performed at the Chelsea Hospital for Women yearly for the last 25 years; the continuous line shows strikingly the enormous increase in these operations. The number of deaths annually is also shown, and the dotted line shows how the percentage of mortality has progressively fallen from 30 per cent. in 1886 to 3 per cent. in 1910. In Chart II. I have selected four typical classes of operation—viz., ovariotomy, hysteropexy, operations for inflammatory tubal disease, and hysterectomy for fibroids; and in each case I have recorded the number of operations performed during five periods of five years each, together with the number of deaths and the percentage mortality during each period.

I should state in passing that the figures given for the years 1886–88 and 1890–94 are incomplete, for in those days there was no registrar, and the only way of obtaining records was to go through the case books; and some of the case books for those years are missing from the hospital archives. In the year 1895 the hospital was reorganised, and Dr. Comyns Berkeley, now surgeon to the hospital, was appointed registrar; from that year onwards there has always been an

CHART I.—*The Progress of Abdominal Surgery during 25 Years at the Chelsea Hospital for Women.*



The dark line shows the total number of abdominal operations in each year. The dotted line represents the mortality per cent.

* A communication read before the Clinical Society of Manchester on Oct. 17th, 1911.

excellent summary of the medical and surgical work done, compiled by the registrar for the annual report.

Other hospitals could doubtless furnish an equally instructive picture of progress. I have chosen this hospital because I know it best, because its records are open to anyone to examine, and because I believe that it reflects the progress of gynæcology as faithfully as any hospital in the kingdom. The results shown in these charts are as startling as they are gratifying, and two questions formulate themselves for consideration. First, how has this progress of gynæcology been brought about? Secondly, what benefits has the progress of gynæcology conferred on the community? The answer to the first question is derived from a study of the evolution of modern gynæcology. In discussing the second question I hope to show that the saving of life, great as it has been, has not been the only benefit obtained—perhaps it has not even been the greatest benefit, because, while we may reckon the lives that have been saved in terms of thousands we may compute in tens of thousands those cases where suffering has been relieved, chronic invalidism has been obviated, and women otherwise destined to be a burden on their families have been restored to usefulness and activity.

CHART II.—*The Progress of Four Classes of Operation during 25 Years at the Chelsea Hospital for Women.*

The dark lines show the total number of operations in each period of five years. The dotted lines represent the mortality per cent.

Ovariotomy.

If I had to select the date from which the evolution of modern gynæcology might be reckoned I should take the year 1809, when Ephraim MacDowell, of Kentucky, performed the first successful ovariotomy. Lawson Tait gave this credit to Robert Houstoun, who was born about the year 1664, and who read before the Royal Society in 1724 a paper entitled "An account of a Dropsy of the Left Ovary of a Woman aged 53, Cured by a Large Incision made in the Side of the Abdomen by Robert Houstoun." Reading the interesting summary of this paper quoted by Lawson Tait,[2] I am led to the conclusion that the operation should properly be included in the category of tapping, as there is no internal evidence that the cyst itself was actually removed. Therefore, whilst I concur heartily in preserving the name of Dr. Robert Houstoun on the roll of fame, I feel I must accord to MacDowell the honour assigned to him by the medical profession in America, in the title "Father of Ovariotomy."

Those whose sense of nationality makes them crave for British credit in the inception of ovariotomy, may find comfort in the fact that John Hunter in 1786 was the first to point out deliberately the feasibility of the operation. In his surgical lectures, speaking of ovarian cysts, he says:—

> Tapping is only a palliative cure, and a large trocar is required, as the fluid is generally gelatinous, and then only one cell is opened. If taken in the incipient stage, they might be taken out, as they generally render life disagreeable for a year or two and kill in the end. There is no reason why women should not bear spaying as well as other animals. It would simply be opening the cavity of the abdomen, which we often do without inconvenience in healthy constitutions.

After MacDowell's case there were several others recorded from time to time. MacDowell himself operated 12 times, with eight recoveries. But the profession as a whole viewed such performances either with scepticism or with more or less veiled disapproval; and it is a pleasure to record, before a Manchester audience, the fact that the next important advance was made by a Manchester man, Dr. Charles Clay. He performed his first successful

operation in 1842, and in all he operated on 395 cases, with 101 deaths, his mortality being thus about 25 per cent. Lawson Tait paid a generous and well-deserved tribute when he said that "it was Clay of Manchester who first showed that ovariotomy could be made an operation more justifiable by its results than any of the major operations of surgery."[3]

It was while Clay was at work that chloroform anæsthesia was discovered and introduced, and there can be no doubt that anæsthesia was the first of the important factors that made abdominal surgery possible. And yet in 1863, when he had performed 108 ovariotomies with 74 recoveries, he appeared to be distinctly doubtful of the value of anæsthesia, for in a paper entitled "Observations on Ovariotomy" we find this curious passage[4]:—

With regard to the use of chloroform I am not certain if this agent has really added to the success of ovarian operations. The first 14 of my cases were undertaken before it was discovered, and of these 14, 9 recovered. But though I willingly admit the almost impossibility of obtaining the consent of females (at the present time) to submit to so formidable an operation without the aid of this valuable agent; and though I am equally convinced that chloroform is of itself one of the greatest boons to suffering humanity, yet, if it could be accomplished, I should infinitely prefer to operate without it, as the patient would bring to bear on her case a nerve and determination to meet so great a trial, which would assist beyond all value the after-treatment; it would also relieve the case from that most distressful retching and vomiting so common after all abdominal operations where it is used to the extent that it is required in ovariotomy.

We may imagine that Clay would have hailed with unfeigned gladness the discovery of spinal analgesia.

This is not so much a historical review as a meditative retrospect. I will not attempt, therefore, to name all those who with untiring patience and unfailing courage helped to win the battle of surgical progress against the forces of prejudice, partisanship, and pusillanimity arrayed against them. Let it suffice that we recall with gratitude the names of Baker Brown and Thomas Keith, who paved the way for future success by the introduction of the intraperitoneal method of treating the stump. Furthermore, I will not go into details of the steps by which the operation was gradually made safer and safer. There were the advocates of the long incision and the short incision; those who used clamps and those who used ligatures, and these again formed two camps, the long-ligature men and the short-ligature men. But while the technique of the operation was gradually being worked out and improved, the mortality still remained distressingly high. To the late Sir Spencer Wells has been justly attributed a large measure of the credit for establishing the operation of ovariotomy on a firm basis; yet in 1878, when he had completed 900 cases, the number of deaths amounted to 221, giving a mortality of 24·5 per cent. This was only a shade better than Charles Clay's mortality of 25·5 per cent. for 395 cases. In the last 100 of Spencer Wells's cases there were 17 deaths. Such results in these days would make the profession shudder, and might well send the operator from surgery to sheep-farming. In our Chelsea records the mortality from 1885 to 1890 was down to 12·8 per cent; and if we ask what brought this about I should answer without hesitation that it was the introduction of antiseptics.

The antiseptic system—or Listerism, as it used to be called—was not, of course, ideal; indeed, it had many palpable disadvantages, and if it had not evolved into something better abdominal surgery would have remained severely handicapped. Many of us can remember the ovariotomies in the old Manchester Infirmary years ago; the carbolic spray theoretically catching and killing hypothetical aerial germs, but actually drenching, irritating, and cooling the abdominal viscera; the carbolic lotions that roughened our hands and the patient's skin; the iodoform that was dusted over wounds and into cavities with a generous disregard of cost and a reckless indifference to iodoform poisoning. We can remember how these ovariotomies were performed with a kind of mystic secrecy worthy of the rites of the Masonic craft; spectators were excluded, and the general ward was too unhallowed for these patients. And yet they died with a tragic frequency.

Compare then with now. At the present time abdominal operations are performed before many spectators, and the patients in our large hospitals are nursed in the general ward. At the Chelsea Hospital for Women the mortality has dropped in 25 years from 12·8 per cent. to 3·4, and the results in general hospitals are practically as good. Comparing my own cases at Chelsea and at the Prince of Wales's General Hospital, Tottenham, I find that at Chelsea from 1906 to September, 1911, I had 71 cases two deaths, or 2·8 per cent.; whilst at Tottenham during the same period there were 91 cases with three deaths, or 3·3 per cent.

What an interesting commentary on the words of Tyler Smith, uttered just 50 years ago from the Presidential chair of the Obstetrical Society of London, when he said[5] "In the long run, I believe, the results cannot be favourable either in general or in special hospitals." If Tyler Smith was pessimistic his pessimism was at least well grounded, for it was based on the liability of patients to develop peritonitis after ovariotomy; and he recognised peritonitis as "a disease closely resembling puerperal or surgical fever and due commonly to some poisonous external agency." If he could have foreseen that this disease was preventable he would doubtless have been more optimistic; and this leads me to point out that this is precisely the key to the whole situation. Our results to-day compare favourably with those of 25 years ago because peritonitis—i.e., sepsis—has been practically conquered. Lister showed the way when he introduced antiseptics, and the crowning triumph of Lister's antisepsis was that it gave birth to asepsis.

I have dealt at some length on the evolution of ovariotomy, first, because it was this operation that opened up the field for other operations on the pelvic organs; and, secondly, because nearly all the light that has illuminated the problems of gynæcological pathology was thrown into the abdomen through surgical incisions. In the departments of medicine and surgery the post-mortem room has been a full-flowing fountain of knowledge; but in the realm of gynæcology incomparably greater results have been derived from the operating theatre.

Extra-uterine Pregnancy.

Take, for instance, the subject of extra-uterine pregnancy. In spite of necropsies, the facts that were known about extra-uterine pregnancy were meagre in the extreme before patients suffering from this dangerous condition were operated upon. In the text-books of our student days, such as those of Thorburn and of Hart and Barbour, hæmatocele and hæmatoma of the broad ligament were described as if they had no relation to extra-uterine pregnancy; in fact, in the differential diagnosis of extra-uterine pregnancy one of the conditions from which we were told to distinguish it was pelvic hæmatocele!

Nearly 50 years ago—or to be precise, in 1863—John Marshall showed a specimen of tubal gestation before the Obstetrical Society of London.[6] It had been removed post mortem, and in the words of Marshall,

An inquest was held upon the deceased, but it being difficult to trace any direct connection between the administration of any abortifacient drug and the post-mortem appearances, and still more difficult to ascertain from whom the drug had been purchased, a verdict of "Death from natural causes" was returned by the jury.

The discussion that followed was marked by an instructive difference of opinion between an obstetric physician (Dr. Graily Hewitt) and a surgeon (Mr. Spencer Wells) as to the chances of saving such a patient by operation. I quote from the Transactions:—

Dr. Graily Hewitt had grave doubts as to the practical feasibility of carrying into effect any operative measures for the relief of these cases of rupture in Fallopian pregnancy. The condition of the parts was peculiar, the number of blood-vessels to tie was considerable, and the condition of the uterus and its appendages wholly different from that present in cases where ovariotomy is practised safely. But this was not all. The chief obstacle lay in the difficulty of diagnosis. ..... Peri-uterine hæmatocele he would mention as one of the conditions not rarely presenting symptoms very closely identical with those of rupture of an extra-uterine pregnancy.

Here is a picture for us; so near the truth and yet so far; here is a man living in the dense darkness of a fog with the clear sunshine only a few yards above him. Then speaks the surgeon:—

Mr. Spencer Wells said that if it were certain that a patient was dying from internal hæmorrhage, owing to a rupture of the sac of a tubal pregnancy, he could see no sort of difficulty in the way of a surgical operation. The Fallopian tubes and vessels in the hard (*sic*) ligament would be divided and secured exactly as in every case of ovariotomy. The operation would be extremely simple; what the result would be was quite another question.

Verily, as Tennyson has it, "Knowledge comes, but Wisdom lingers." In spite of Spencer Wells's clear expression of opinion as to the practicability of operation, women went on dying unrelieved and without any attempt being made to save them. In 1876 Parry[7] could still write as follows:—

From the middle of the eleventh century, when Albucasis described the first-known case of extra-uterine pregnancy, men have doubtless

watched the life ebb rapidly from the pale victim of this accident, as the torrent of blood is poured into the abdominal cavity, but have raised no hand to help her. Surely this is an anomaly, and it has no parallel in the whole history of human injuries. The fact seems incredible, for if one life is saved by active interference, it may be triumphantly pointed to as the first and only instance of its kind on record. In the whole domain of surgery—for we cannot look to other than surgical measures under the circumstances—there is now left no other field like this. ..... The only remedy that can be proposed to rescue a woman under these unfortunate circumstances is gastrotomy—to open the abdomen, tie the bleeding vessels, or to remove the sac entire.

Even these impassioned words found no practical response till seven more years had passed, and then Lawson Tait came forward as the champion of these dying women and deliberately and successfully operated for a tubal rupture. There can be no doubt that his example led to the saving of many thousands of lives. At the Chelsea Hospital for Women, from 1895 to 1910, 156 operations were undertaken for extra-uterine pregnancy, with five deaths, a mortality of 3·2 per cent., and in my own practice I have had occasion to operate in 87 cases with three deaths, or 3·4 per cent. If we multiply such experiences by those of other operators we get some kind of idea of the debt that mankind owes to Lawson Tait.

Turning to the question of the light that surgery has thrown upon the pathology of these conditions, we find that in 1889 Bland-Sutton described for the first time the tubal mole, under the title of "An Apoplectic Ovum from the Fallopian Tube."[8] The importance of this communication cannot be over-estimated, for it was not only the first correct explanation offered of rupture of the tube, but it also gave us a definite criterion by which to judge whether or not a hæmorrhage into the peritoneal cavity was due to an extra-uterine pregnancy.

In 1894 the late J. W. Taylor, of Birmingham, described an intra-peritoneal hæmatocele as being produced by a blood-drip through the still open fimbriated extremity of the tube[9]; and I may mention in passing that this able and lamented surgeon's monograph on the subject[10] is still the most enlightening and complete account of it that we possess. His observations on hæmatocele were confirmed and expanded by Cullingworth in several valuable communications; Sampson Handley in 1902 described the para-tubal hæmatocele[11]; Catherine Van Tusschenbroek described in 1899 the first authentic case of ovarian pregnancy[12]; and by the work of Berry Hart, Freeland Barbour, Clarence Webster, and many others, there is no field in gynæcological pathology that is now so well explored and so well understood as that of extra-uterine pregnancy.

The Surgery of Inflammatory Disease of the Tubes.

Those of us who were students 25 years ago must have a vivid recollection of the confusion into which our minds were thrown when we attempted to understand the terms "perimetritis" and "parametritis." Those who wrote text-books had no clear conceptions on the subject of pelvic inflammation; how, then, could they convey any clear ideas to us? Bernutz, in 1879, was the first to call attention to the fact that "perimetritis" was due to tubal inflammation; and in the same year Lawson Tait performed the first operation for the removal of inflamed tubes. For some years he went on with these operations, encountering considerable opposition. In 1882, he showed before the Obstetrical Society of London specimens from 15 cases of hydrosalpinx and pyosalpinx, which he exhibited "to show that the criticism offered against him of removing uterine appendages unnecessarily was unfounded." In 1883 he could record 62 cases without a death; and in a discussion on this paper[13] Dr. Robert Barnes made the significant statement that "no doubt there would be some opposition to his views—timid opposition, on the one hand, from the *far niente* school; violent from the dogmatic." In this discussion several speakers took up the position that conditions such as hydrosalpinx, which did not threaten life, did not justify operation; and in his reply Lawson Tait showed how far he was in advance of current medical opinion when he said that "we could not stop short of dealing with matters that affect life only. Hydrosalpinx was a frequent cause of the most intense suffering, and, therefore, he would, and did, remove it by surgical operation without hesitation."

Ten years passed, and still Lawson Tait's views were not accepted in high places. In 1892 Cullingworth read before the Obstetrical Society of London an important paper[14] on "The Value of Abdominal Section in Certain Cases of Pelvic Peritonitis." It is most instructive to read the discussion that followed, in the light of the teaching and practice of the present time. Some of the speakers, and among them the leading obstetric physicians of the day, offered the keenest opposition to Cullingworth's views; and it is refreshing, by way of contrast, to read the enlightened remarks of such men as Mayo Robson, Peter Horrocks, Henry Gervis, John W. Taylor, and Heywood Smith. Mayo Robson, with a surgeon's insight, compared these cases with recurrent attacks of inflammation of the vermiform appendix. "If," he said, "they did not hesitate in such cases to remove the appendix, why should anyone argue that a similar, though larger, collection of pus, in the Fallopian tube, should not be treated on the same principles?" Heywood Smith recalled the fact that some months previously two of the speakers "had issued a quasi-authoritative manifesto, wherein they feebly attempted to apply the brake to the advanced gynæcology of the present day."

But the wheel of progress was already turning in such vigorous fashion that the said brake had practically no effect; and we may claim for Cullingworth that on that day he added no little to the momentum of this wheel, for afterwards no authoritative attempt was made to check its revolutions, and from that paper we may date the general adoption of the view he upheld. Cullingworth's mortality was 18 per cent. in his first 50 cases; in his second 50 it was 8; in his last 25 cases he had no deaths; and the records of the Chelsea Hospital for Women amply support his contention that experience must lead to greatly diminished mortality. From 1885 to 1890 (before Cullingworth's paper was read) the mortality at Chelsea was 33·3 per cent. on 12 cases; from 1906 to 1910, 363 operations for inflammatory disease of the appendages were performed, with a mortality of 1·3 per cent. Perchance in the Elysian fields Charles Cullingworth may be able to receive this tribute; he may "see of the travail of his soul, and be satisfied."

Hysterectomy for Fibroids.

Once more, in tracing the origin of this operation, we must dip into the semi-distant past; and once more we must bring into the light the name of Charles Clay, of Manchester. To him belongs the double record of having performed the first complete extirpation of the uterus and ovaries by the abdominal route, in January, 1844, and also of having done the first successful hysterectomy for fibroids. The plan he adopted in the latter case was to tie a ligature tightly round the cervix and cut the ends short, thus performing the first intraperitoneal hysterectomy. This was in January, 1863, and the Obstetrical Transactions for that year contain an interesting woodcut of the uterus after removal. He was led to adopt this procedure from his experience in ovariotomy; but in the hands of subsequent operators nothing but failure resulted from this method.

In April of the same year Koeberlé, of Strasburg, performed his first hysterectomy; and to him is due the credit of having brought the operation into the range of practical surgery by the introduction of the extraperitoneal method of operating by means of the serre-nœud. The method remained the best for many years, although the resulting mortality was still very high. In London, Granville Bantock and Knowsley Thornton were among the most successful of its exponents. It was practised at the Chelsea Hospital for Women as late as 1895, and as far as I have been able to trace the records from 1885 to 1895 there were 21 cases, with 9 deaths—a mortality of 42 5 per cent. In 1893 and 1894 I assisted some of my seniors at this operation, but I never performed it myself, for happily by the time that I did my first hysterectomy we had been shown a more excellent way.

Meantime, another method of operating for fibroids had been introduced by Lawson Tait—namely, the removal of the ovaries and tubes; the object of this was to cause a shrinkage of the fibroid tumours, on the analogy of what was supposed to happen at the menopause. In advocating this method, Tait was chiefly influenced by the high mortality of what appeared to be the only alternative plan—viz., hysterectomy by the extraperitoneal method; and it is interesting to note that this usually clear-sighted man was led to express a curiously erroneous forecast of the future of hysterectomy. He said, in supporting the claims of the removal of the ovaries,

Considering that hysterectomy has at present, and (as the use of the clamp in this operation is inevitable) is ever likely to have, a very heavy mortality I think we are bound in all cases of doubt to give our patients the benefit of that doubt, and to resort to the less formidable operation in the first instance.[15]

In 1892 Baer, of Philadelphia, introduced the most important change in the history of operations for fibroids by his plan of ligaturing the uterine arteries and leaving the cervix free. This, as Bland-Sutton has pointed out,[16] revolutionised the surgical treatment of uterine fibroids, and no one has done more than Bland-Sutton himself to establish the operation on a secure footing. He joined the Chelsea Hospital for Women in 1895, and his influence is clearly shown in Chart II. In 1891 to 1895 rather more than 12 hysterectomies were done, with a mortality of over 40 per cent.; in the next five years the number rose to 150, and the mortality dropped to 10·6 per cent.; in 1901 to 1905 there were 345 hysterectomies, with a mortality of 5·2; and in 1906 to 1910 the number stood at 487, with a mortality of 1·8.

I doubt if the whole range of surgery could show any other operation that presented such an extension of scope and such rapidly diminishing mortality. I feel sure that all my colleagues at Chelsea would concur with me in assigning a large share of the credit for these results at our hospital to the presence of Bland-Sutton on the staff.

Among the pathological questions on which the surgery of fibroids has afforded us valuable information we may mention the subject of fibro-adenoma of the uterus, the mode in which degenerative changes in fibroids are brought about, the association of pregnancy with the condition known as red degeneration, and the association of fibroids with disease of the ovaries and Fallopian tubes.

There are other developments of gynæcology that would afford a profitable and interesting study—for example, the evolution of operations for carcinoma of the uterus and for the surgical treatment of displacements; but I have already taken up so much time in unfolding this part of my subject that I must omit them, and pass on to a brief consideration of the second question to which I wish to invite your attention.

What Benefits has the Progress of Gynæcology Conferred on the Community?

Chart I. shows us that in the five years 1885–86 to 1889–90 the number of abdominal operations at the Chelsea Hospital for Women was something over 122; in the five years 1906–10 the number was 1880, a difference of about 1750. What happened to these 1750 women that were not operated upon 20 years ago? We can say without hesitation that a number of them died for the want of operation. Some of them would be cases of ovarian tumours, because, as we see from Chart II., about three times as many ovariotomies were done in the last five years as were done in the first five, although even in those earlier days ovariotomy was a definitely recognised operation. Other fatal cases would be those of extra-uterine pregnancy; it might be said that these did not die for want of operation, as they stood a very good chance of dying if operated upon. At any rate, the five cases done in 1886–90 all died. But in 1906–10 there were 59 such operations with one death, and a large proportion of these cases would certainly have died without the help of surgery. Then there were patients with inflammatory disease of the appendages; many of these conditions are, of course, not fatal, but there is quite an appreciable percentage of cases of pyosalpinx that destroy life. In our first five years 12 operations were done for inflammatory disease; in the last five years, 363; of these 5 died, but on the modest computation that in 10 per cent. of cases inflammatory disease proves fatal, 35 would have died without operation, against 5 in spite of it.

Operations for displacement do not come into consideration at all here, because the condition is never fatal. In the case of hysterectomy for fibroids, however, we again come to a group in which an appreciable number of patients die if not surgically relieved; and of such operations there were 14 in the first five years, against 487 in the last five. I have not gone into the question of carcinoma of the uterus, but in this department we should find a large number of cases of the direct saving of life by surgical intervention.

I think that I have said enough to show that the progress of gynæcology has led to the saving of many lives; but this could be said of the gynæcology of 25 years ago, although the proportion of lives saved to-day is much larger than it was then. The striking feature, however, in the evolution of the last 25 years is the phenomenal extension of the scope of operations, not for the saving of life alone, but for the relief of suffering. At a time when abdominal surgery of all kinds was attended by a high rate of mortality it was wise and practical advice to recommend patients to endure their sufferings with Christian resignation rather than face the risks of surgery, and patients might have quoted with justification the saying of King David, "Let me fall into the hands of God, rather than into the hands of men."

Let us look a little more closely at some of these operations designed to relieve suffering. We need not consider the cases of ovarian tumour, ruptured tubal pregnancy with free hæmorrhage, and carcinoma of the uterus. In such cases we must operate for the direct purpose of saving life. Consider such conditions as *tubal inflammation* and *tubal pregnancy with restricted hæmorrhage*. That some of these cases may prove fatal is true enough, but the important reason for operating on such cases to-day is not that the patient's life is directly threatened, but that the alternative to operation is prolonged illness, constant suffering, more or less complete invalidism, and disablement. Some of these women in the poorer classes are the breadwinners, and disablement is for them a worse evil than death.

Thirty years ago it was only the few men that had the surgical genius of a Lawson Tait who were justified in taking up the position he adopted, and in saying, in the words I have already quoted, "We cannot stop short of dealing with matters that affect life only." The majority of those who opposed his views were probably quite justified in the interests of their patients in refusing to operate on such cases; they doubtless did the kindest thing in leaving them alone. But think of the amount of suffering saved, the workers that have been restored to the position of earning their livelihood, the relief to the community in the conversion of dependent invalids into sound members of the body corporate; think of all this amount of good done as represented by the 863 cases of operations for diseased appendages in the last 15 years at the Chelsea Hospital for Women.

It was objected formerly, and I believe that the objection might be found still in some places, that these women remained chronic invalids, that they were unsexed, and rendered unfit for wifehood; that at the best they remained hysterics, and at the worst they became lunatics. These objections were theoretical, and I was able to show last year, from a detailed investigation of the after-results of these operations, based on 200 cases in which both ovaries were removed,[17] that 70 per cent. of the patients regained perfect health and vigour and retained their sex instincts, and only two patients developed mental symptoms. Further, from a study of the after-results of abdominal operations generally it was shown that these figures correspond closely to those of cases in which one or both ovaries had been preserved.

There is another aspect of the question, which we must think of in a chastened spirit, because it is a terrible reproach to the medical profession. Many patients with chronic pelvic disease suffer intermittently; they are seldom acutely ill, but they are never completely well; and because there is not much to show for their sufferings they have been treated as neurotics and almost as malingerers; they have been drenched with bromides and valerian; they have been sent from spa to spa; they have been driven to seek relief in alcohol or morphia; or they have found a doubtful haven among the faith-healers and the "Christian Scientists." I contend that we have no right to describe a woman as neurotic unless we can be certain that she has no organic disease.

A few words about *uterine displacements* and their surgical treatment. These are conditions that are not fatal, and operations undertaken for their relief should have no mortality. As a matter of fact, in the 584 cases operated upon at Chelsea in the last 20 years there were 2 deaths—one from pneumonia and one from diabetic coma. Such deaths might, of course, occur without operation. The value of these operations consists partly in the fact that many patients are cured who cannot be treated by other means (for example, cases of adherent retroversion and some cases of prolapse and procidentia); and partly in this, that patients are saved from years of pessary treatment. I hold that pessaries are a necessary evil—that is, they are necessary sometimes, but evil always. If I could avoid it, I would never use one. At present I see no prospect of consigning them one and all to the bonfire, but this may come to pass in the future, and meanwhile I take such comfort as I can from the thought that at least no pessary will be known by my name.

Now if by means of a safe operation a patient can be saved

from the unpleasantness of frequent examinations, from the discomforts of discharges and their attendant douchings, and from being chronically under the doctor's hands, and if patients desire such relief, surely they are entitled to have it. The radical cure of hernia is considered justifiable, to obviate the constant wearing of a truss; why not the radical cure of a uterine displacement to obviate pessaries? Well, the progress of gynæcology has opened up this field of relief to women, and I think that the table of hysteropexies in Chart II. represents a very great amount of benefit in the relief of suffering and in the emancipation from disablement.

If we turn to the subject of *uterine fibroids*, we again have a condition in which a directly fatal result is produced in only a minority of cases, but the amount of suffering and disablement is appalling. What a boon to the sufferers and what a gain to the community is expressed in the 982 cases of hysterectomy for fibroids performed at the Chelsea Hospital for Women in the last 15 years. Twenty years ago the mortality was 35–40 per cent., and physicians were amply justified in advising patients whose lives were not directly threatened to endure their sufferings rather than resort to operation. Of course, this procedure reacted on the mortality, because if operation for fibroids is delayed until it is a question no longer of merely relieving suffering, but only of saving life, the mortality must necessarily be much higher. Still, even in uncomplicated cases the mortality was high in those days, and patients seldom yearn for death as a means of relief from suffering: it is, after all, better to live as an invalid than to die cured.

Now when a patient with fibroids has to be told that the resources of medicine are all spent and that the succour of surgery is more cruel than kind, it is a great comfort to be able to hold out some kind of hope, however unsubstantial; and so a fairy tale was built up and decorated to represent a scientific theory to the effect that the menopause was the natural cure for fibroids. And patients were told in all seriousness and good faith, "You must wait for the change of life and then these tumours will shrink and disappear and you will get well." And the patients went on patiently draining their life-blood away, carrying about enormous tumours that prevented them from moving about, hoping against hope that the delayed menopause would arrive, like some millennium, to give them peace. Some of them survived the worst troubles and escaped with their lives, though at the price of being permanent invalids; others found that the menopause, when it came, came not to bless but to curse, bringing in its train degenerative changes, infection, sepsis, and death.

Now the tragic thing is that to-day, when the mortality after operations for fibroids has dropped almost to vanishing point in uncomplicated cases, and when the operative risks in serious cases are less than the risk of leaving things alone, the hoary myth survives; and whatever moral comfort it may have given in earlier years, it is certain that in later years it has wrought endless mischief and inflicted a grievous and totally unnecessary amount of suffering. I may be told that some fibroids settle down and ultimately cause no trouble. With all my heart I grant it; but how many? And—

> "Who can so forecast the years
> Or find in loss a gain to match?"

How are we going to tell which of our patients in this lottery are going to draw the few prizes and which are destined for the many blanks? Why should we condemn them to suffer for years with a doubtful prospect of cure and a probability that they will have to undergo operation in the end? With such a table as that in Chart II. before me, showing that in the last five years 487 hysterectomies were performed, with a mortality in all cases, serious as well as simple, of 1·8 per cent., I am emboldened to take up the position that all fibroids should be operated upon in the early stages unless some weighty reason to the contrary can be shown. If operation is safe before complications have set in (and I think that the truth of this has been demonstrated); if cases that are left suffer seriously and are severely incapacitated (a proposition that requires no demonstration); if the majority of cases that are left come to operation in the end (and I think that this proposition is equally true); and if, finally, the operative risk is much greater when complications have set in (a fact that no one will dispute),—then I hold that we are not justified in refusing relief in the early stages, in condemning patients to years of suffering and incapacity, and in exposing them after all to the much greater operative risk by waiting till life is seriously threatened.

When we look back at the evolution of gynæcology during the last 25 years we see that many things are now plain that were then shadowy and ill defined; we see that our knowledge of the pathology of ovarian and uterine tumours, of pelvic inflammation, and of tubal pregnancy has been enlarged and rendered more precise; we realise that we owe this heritage to the courage, the patience, and the insight of the pioneers of gynæcological surgery. We see, further, that this surgical activity has resulted not only in rich additions to our stores of knowledge but in an immense saving of valuable lives, in an enormous diminution in the sum-total of human suffering, and in the raising of an untold number of women from beds of invalidism to active happy, healthy life.

But if we may look back with pride we must look forward with humility; there is so much still that we do not know; there are so many lives still that are not saved. But the success of the past is the earnest of the future; and every search for further knowledge, every steadfast endeavour in applying our knowledge to our practice, will constitute

> "a closer link
> Betwixt us and the crowning race
> Of those who, eye to eye, shall look
> On knowledge, under whose command
> Is earth and Earth's, and in their hand
> Is nature like an open book."

Upper Wimpole-street, W.

METASTATIC SUPPURATIVE CYCLITIS OCCURRING IN A WOMAN WITH PYÆMIA; ABSCISSION; RECOVERY.

BY SIR WILLIAM COLLINS, M.S., M.D., B.SC. LOND., F.R.C.S. ENG.,

SENIOR SURGEON TO THE LONDON TEMPERANCE HOSPITAL AND TO THE ROYAL EYE HOSPITAL.

A MARRIED woman, aged 54, who was admitted into the London Temperance Hospital on April 5th, 1911, complained that she had been ill for several weeks with general loss of energy, accompanied for the last fortnight by "chills and flushes" and "pains all over her." She had vomited several times. She had had rheumatic fever 20 years ago. There were scars over the right mastoid and right angle of the lower jaw dating from childhood. On admission she appeared frail, ill, and anæmic. Her temperature was 103° F.; the tongue was red, dry, and glazed; the pulse-rate was 108, and the respirations were 26. The most salient symptom was proptosis of the right eye. The conjunctiva was injected and inclined to be chemosed; tension full; cornea steamy; pupil immobile; iris woolly; some opacity on the lens capsule. Vision, large objects only; movements of eyeball restricted and very painful. An elastic tender swelling was found on the right side of the neck over the upper part of the carotid. A note made at the time said: "Suggestive of inflammation round a thrombosed jugular vein." There was some impaired resonance at the right apex. The heart sounds were clear but weak; abdomen *nil*. The patient complained of pain in the left knee, and there was some bright redness and œdema over that joint.

On April 6th, under ethyl chloride, I incised the cervical swelling, letting out half an ounce of watery pus. I diagnosed suppurative iridocyclitis of the right eye and advised abscission. The proptosis and chemosis had greatly increased, and the pain prevented sleep. On the 7th, under chloroform, I abscised and eviscerated the right eye and washed out the scleral cup with hot sterilised water. From the 8th to the 12th the patient was greatly relieved, and her temperature fell. Some fluctuating swellings in the left arm appeared

which were incised and pus was evacuated. Her general health was improving under generous diet. The pain had gone from the left knee. The abscess in the right cervical region required further opening and drainage. The right orbit quieted down and in a month the patient left the hospital quite well.

The abscised portion of the right eye showed well-marked suppurative cyclitis. There was a coronet of pustules jutting out from the intervals between the ciliary processes. The pathologist reported that short chain streptococci were found in the pus from the neck.

The sequence of events appeared to be a pyæmic condition arising from the abscess in the right side of the neck, not very acute in its character and containing watery pus, possibly of old tuberculous gland origin. Thence absorption appears to have taken place with metastatic cyclitis, which became the dominant feature of the illness, metastatic abscesses in the left arm, and a threatened synovitis of the left knee. The lungs, however, did not give any evidence of a breaking down lesion.

In such a condition of proptosis and chemosis it is not always easy to decide between an intra-ocular and an extra-ocular cause, an iridocyclitis leading on to panophthalmitis or an orbital cellulitis which may lead to meningeal complication. In this case the woolly iris, the suggestion of lymph on the anterior capsule and the absence of a "brawny" condition of the lids, despite the exophthalmos and restricted movements, led me to infer a suppurative iridocyclitis.

A careful observer of the case had not without some reason suggested septic thrombosis of the cavernous sinus and of the internal jugular vein as explicative of the associated ocular and cervical symptoms. The case was one of extreme clinical and pathological interest and the immediate relief afforded by the abscission was very marked. I prefer abscission to excision in such cases as being less likely to infect the orbital tissues.

URETERAL GRAFTS.

BY A. CHIASSERINI, M.D.

(*Laboratory of Surgical Pathology, Rome.*)

THE surgery of the ureter has lately acquired a standing of its own, as the operations and experiments upon such an important structure have become more and more frequent, in consequence either of surgical affections of the reno-vesical ducts (stones, tumours, inflammations, &c.) or, more often, of neoplasias of the pelvic organs spreading along and infiltrating at the same time the ureters.

The surgical procedures upon these range from anastomosis (end-to-end, lateral anastomosis, end-in-end, &c.), when the ureter has been cut across and the two ends can be drawn near each other, to the various methods of implantation of the ureter in the different organs (bladder, rectum or sigmoid, vagina, urethra, skin, ureter of the other side). But ureteral anastomosis, as much as implantation of the ureters, has nearly always given uncertain or unfavourable results and rarely good ones; this, either because of the formation of urinary fistulæ followed by an ascending infection or the occurrence of a stenosis with consecutive hydronephrosis and pyelonephrosis.

This being the case, many surgeons thought of replacing the piece of tube which had been cut away either with some inorganic material, as glass tubes (Casati, Baori), tubes made of silver and caoutchouc (Israel), or with whole organs taken from the surrounding structures. These were the first experiments of transplantation applied to such a vital and delicate structure as the ureter, and they were tried on men and animals. Casati, Boari, and Van Hook cut a flap out of the bladder and sutured it in the shape of a tube to the proximal end of the ureter. Rydygier did the same with a flap of skin. Fenger and Bacon, Poggi and Tizzoni, D'Urso and De Fabi, Esau, and Moskowicz employed loops excluded from the bowel but still attached to their mesentery, while Giannettasio, Rydygier, and Franke transplanted in the same way the appendix, and D'Urso, De Fabi, Flörcken, and Stubenrauch the uterine horns of bitches. The function of the ureters was generally impaired or destroyed because of the frequent stenosis and infection, but the transplantation of the uterine horns gave better results.

In the meanwhile new surgical procedures were invented in order to make the work of transplantations more practical: bones, periosteum, joints were transplanted in the regions where such structures were needed. Carrel, Guthrie, and Stich were the first to attempt successfully, with a special operative technique, vascular grafts. The tubular shape of the vessels and their different width could have made of them an excellent material for substituting several hollow structures of the body. According to this principle Payr used them to drain the cerebral ventricles in cases of hydrocephalus, while Baumgarten, having tied a piece of vessel at the two ends, so that no blood could pass through it, observed a proliferation of the cells of the intima. The conclusion was that the presence of circulating blood in the vessels did not seem absolutely necessary for their life.

Such grafts were then used for other purposes: to cure hypospadias (Tanton), to replace the common bile duct in dogs (Tietze). From this to the vascular transplantation of the ureter was but a short step. In fact, in 1908, Melchior, and afterwards Rick, Holbauer, and Klepp tried (with success according to them) to replace in dogs a piece of ureter cut off with a segment of vessel. The same thing was done by Tuffier (uretero-phlebo-enterostomy) in a woman. The last-named surgeons did not make any histological research on the graft after a certain time had elapsed, whereas Tietze and Flörcken found that the transplanted vessel soon was replaced by connective tissue. New experiments were needed to decide upon this important subject. Therefore, on the advice of Professor Alessandri, and in conjunction with Dr. Dominici, I began last November a series of experiments on the ureter of dogs with vascular grafts. Dr. Dominici gave an account (regarding 10 cases) before the Medical Academy of Rome (April, 1911) and in the Folia Urologica (October, 1911) of the operative technique followed, and drew the conclusions which could be inferred from the macroscopical examination. On my own account I made eight more experiments and examined histologically sections taken from each of the 18 cases. In experimenting I made use sometimes of pieces of vein (external jugular, femoral, and saphenous), sometimes of the carotid artery. I reached the ureter by the extra-peritoneal route and sutured the two ends of the ureter to the transplanted vessel by Carrel's method (slightly modified), having first cut away a piece of ureter somewhat shorter than the graft. In 12 cases the continuity between the two ureteral ends was re-established, but a stenosis or a complete occlusion corresponding to the vascular graft was the usual result. Briefly the conclusions that I came to are as follows: 1. There is a possibility of the vessel introduced between the two ureteral ends becoming firmly united to them. 2. The piece transplanted, a few days after the operation becomes shortened so as to draw the two ureteral ends nearer together. 3. The graft becomes thicker and hard, while the lumen is nearly obliterated. 4. The stenosis causes a stoppage in the flow of the urine with consecutive dilatation of the canal of the ureter and hydronephrosis.

The histological examination thus confirmed what could have been inferred from a macroscopical survey; but at the same time it showed a series of vital facts (proliferation of the epithelium and muscular fibres) of some importance. Without discussing these, it is certain, at any rate, that vascular grafts cannot be used to replace a segment of the ureter.

The fact that vascular grafts in vessels (arterial in veins and *vice versâ*) are generally satisfactory, while the same cannot be used to replace other hollow structures on account of their fibro-formative tendency, seemed to me in favour of the idea that a normal functional stimulus is a *conditio sine quâ non* for the life of vascular tissues. But, although the number of these experiments was not sufficient to be absolutely conclusive, the fact that every time I left a catheter in the ureter for several days I was able to observe in the graft evidences of regeneration which were lacking in most cases where no catheter was left *in situ*, counts for something. In these last cases I could only see retrogressive changes. Is it going too far to attribute them to the lack of the normal stimulus—the circulating blood, together with the presence of an abnormal stimulus—contact with the urine? The irritating action of the latter must have contributed to the destruction of the normal tissue of the vessel wall.

Given these considerations and the tendency in surgery to substitute defects of substance with similar tissues (cutaneous

grafts, bone and periosteal transplantations, grafts of whole joints, &c.), I thought of doing the same with the ureter—in other words, of performing ureteral auto-transplantations. The number of these experiments as yet made is too small to allow me to give a definite answer on the practical use of ureteral auto-transplantations, still I think I may call the results satisfactory. I hope to be able later to prove them on a larger scale and to confirm them with the bistological examination.

Rome.

A CASE OF TRICUSPID REGURGITATION.

BY R. O. MOON, M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL FOR DISEASES OF THE HEART, SOHO-SQUARE, ETC.

THOUGH tricuspid regurgitation of organic origin is not particularly uncommon, yet it is so frequently accompanied by a lesion of the mitral or aortic valves or both that a case in which the endocarditis has affected the tricuspid valves only seems sufficiently rare to be worth recording.

A boy, aged 5 years, was admitted into the Hospital for Diseases of the Heart on May 22nd, 1911. There was nothing of importance in the family history. In infancy he had suffered from convulsions, but none after the first year. When 2 years old he had measles, and at 3 he suffered from diphtheria, the attack having been severe; the heart was said to be affected while in the fever hospital, and since then he had always seemed rather weak. Three months prior to admission he had seemed very tired and languid, at times being giddy, and in March he was in the Paddington Children's Hospital for "endocarditis," but remained rather a short time owing to the development of whooping-cough. On admission he seemed dull and apathetic, with a somewhat dusky appearance. The heart's apex beat was in the fifth space in the nipple line. Percussion showed distinct enlargement—dulness extending half an inch external to the nipple line and one-third of an inch to the right of the right border of the sternum; speaking generally, it was rather a flat area of dulness. A long, blowing, systolic murmur was heard all over the præcordial area and at the back, the pulmonary second sound was distinctly accentuated, and there was a cantering rhythm in the tricuspid area. I should mention that when seen in the out-patient department there was a systolic thrill internal to the apex, but this was not detected again while he was in the hospital. The liver was enlarged to within 2 inches of the umbilicus, but there was no tenderness, pain, or pulsation. The lungs presented nothing abnormal.

Soon after admission he complained a good deal of pain in the legs, and a moderate degree of œdema developed there. On June 8th there were dulness and deficient entry of air at the right base up to the angle of the scapula and in the right axilla; there was also considerable œdema in the lumbar region and most of all about the scrotum; in fact, general anasarca but no ascites. He was given diuretin gr. v., t.d.s., with very good results; the urine excreted during the few preceding days had averaged about 11 oz.; after taking diuretin a couple of days the excretion of urine increased considerably, while the œdema very largely disappeared, there being only some fluid at the bases of both lungs. On June 14th the temperature rose to 99·6° F., and on the 15th to 101·8°, returning to normal on the 20th. During this time there was an increase of the cardiac dulness upwards to the upper border of the third rib, and there was a triple sound suggestive of pericarditis in the third and fourth left spaces close to the sternum. On the 27th the œdema had again increased very much, particularly about the face, giving the patient a most typically renal aspect. However, though the urine was examined frequently, there was never more than a trace of albumin to be detected and no casts, so that it was quite clear that the case was purely cardiac. He was then given a mixture of tinct. digitalis. ♏ v.; spt. ætheris nitr., ♏ xv.; inf. scoparii ad ½ ʒ, every four hours, without producing much effect upon the œdema, which, however, was never so great as when it had first appeared. At this time a great trouble was sleeplessness and frequent shouting out at night, which disturbed the whole ward; he was never actually delirious; the shouting was loud and vigorous, but he always had something more or less intelligible to say when the nurse came to him. At first the condition was relieved by chloralamide (gr. x.) with ammonium bromide (gr. v.), but it soon ceased to be effectual, even after increasing the dose. After that occasional doses of nepenthe (♏ v.) were given at night, which calmed him to some extent, but the restlessness and shouting at night remained very marked features of the case. On July 3rd the triple sound at the base of the heart was no longer audible, but the cantering sound in the tricuspid area was still very evident. Just at this time the weather became excessively hot and the child seemed obviously worse, though there was no change in the physical signs, the cardiac action being regular and fairly forcible to within 24 hours of the end, which came on July 8th.

The necropsy, which was performed by my colleague Dr. Russell Wells, showed the following: Chest: 3 oz. of fluid in each pleural cavity. Lungs quite healthy. Heart: weight, 6¼ oz.; a few drachms of fluid in the pericardial sac; slight recent pericarditis at the base. Right auricle: hypertrophied and dilated; markedly muscular. The wall had numerous muscular bands, giving it the appearance of a normal ventricle. Left auricle: practically normal except for a fatty deposit diffused over the whole surface under the lining membrane. Aortic, pulmonary, and mitral valves competent and normal. The tricuspid valve showed recent translucent vegetations on all the flaps of the valve, having the appearance of glue tinted with saffron. Kidneys: right 2¼ oz.; left 2½ oz.; healthy; marked fœtal lobulation. Liver: weight 21½ oz.; well-marked nutmeg appearance. On the pancreas and adjacent tissues there were some little specks of about the size of a pin's head, of a dead yellowish-white appearance, probably fatty necrosis.

Finding the mitral valve normal did certainly come to me as a surprise; the fact that the systolic murmur was plainly heard at the back is generally held to be against the purely tricuspid origin of it; then, again, the accentuated pulmonary second sound seemed to point to the mitral lesion, but in children no doubt one cannot attach much importance to these signs. On the other hand, there was no cough or dyspnœa, and the comparative absence of œdema from the lungs was in striking contrast to the general anasarca. The cantering sound in the tricuspid area which usually points to an abnormal blood pressure in the right ventricle ought, perhaps, to have given the clue to a correct diagnosis.

Green-street, W.

BACTERIAL INFECTION OF THE STOMACH WALL TREATED BY VACCINE-THERAPY.

BY FRANK KENNEDY CAHILL, F.R.C.S. IREL., D.P.H.

THE following case may be of interest to some of the readers of THE LANCET.

The patient, a man, aged 48 years, who consulted me in April, 1910, had been suffering for some 12 months from "foul breath." So great was the social inconvenience that it became almost impossible for him to carry on his business, involving, as it did, intercourse daily with a somewhat fastidious *clientèle*. In his efforts to seek relief he had consulted many physicians and specialists, among the latter a very eminent throat specialist, who declared that he was quite free from nasal trouble, and a dentist who declared that his denture was flawless. I made a very careful general examination and could discover no physical disability save a cystitis of long standing (45 years). This latter the patient informed me dated back to his childhood, when he had been operated on for stone in the bladder at the age of 3 years. A stricture followed the operation, and as long as the patient could remember his urinary stream had been small. There were no symptoms of stone at the time of examination. On passing a No. 4 catheter about two ounces of "residual" urine came away; this was found to contain numerous pus cells, and on bacteriological examination yielded a growth of pure streptococcus.

The patient did not complain of "indigestion" (that much abused term). He had a hearty appetite, but eating or starving he had his "foul breath." The stomach emptied itself in normal time. Gastric chemistry was normal. Having secured specimens from his stomach, the cultivation yielded streptococcus and bacillus coli. There was a possibility that the streptococcus found in the stomach came from

the nose or was due to pyorrhœa alveolaris, but the opinions of the above-mentioned specialists would seem to negative this. So the patient would seem to be suffering from a bacterial infection of the stomach, and it is interesting to note that the streptococcus was found in the bladder also.

I had a "vaccine" prepared consisting of a streptococcus from the urine and a bacillus coli from the stomach in the following proportions representing millions:—

	No. 1.	No. 2.	No. 3.	No. 4.
Streptococcus	5	5	10	20
Bacillus coli...	5	10	15	20

I made the first injection on April 19th, and repeated the injection at intervals of one week, giving in all four doses. By the middle of May the "foul breath" had completely disappeared, and has not returned up to the present, now 17 months afterwards.

The case presents many features of extreme interest to the stomach specialist, but in the course of a short communication I shall refer to one only. Hitherto infection of the stomach walls by the bacillus coli has been noted by gastro-anterologists in obstruction of the pylorus due to malignant disease only, and I have been unable to find in the literature any record of a case in which, though the gastric motility was normal, a bacterial infection of the stomach mucosa by this organism had occurred.

The cystitis in this patient improved, but did not, of course, disappear, and the patient was quite content with the cure of his "foul breath" which, had it continued, would have necessitated his retirement from business. (He has now had the urethral stricture dilated and all pus has disappeared from his urine.)

ROYAL SOCIETY OF MEDICINE.

SURGICAL SECTION.

Caries of Frontal Bone.

A MEETING of this section was held on Nov. 14th, with Mr. CLINTON T. DENT in the chair.

Dr. W. RINGROSE GORE read a paper entitled, "A Case of Caries of Frontal Bone and Intracranial Abscess due to Bacillus Typhosus 11 Years after Attack of Typhoid." The important point arose as to what could be done to prevent these cases of typhoid bone infection. Although not usually fatal in themselves, they might become so from their situation; for instance, an abscess might rupture through the dura mater, and a case of fatal peritonitis had been recorded following a typhoid abscess of the lower end of the sternum. It might be held that patients suffering from this condition were typhoid carriers, the habitat of the bacilli being in the walls of the gall-bladder where they could not be reached by medication or vaccines as they were shut off from the circulation, but from which situation they could occasionally infect the blood-stream. Removal of the gall-bladder had been performed, but the operation in these cases appeared to be a dangerous one. The other alternative appeared to be to try by successive courses of vaccine to create a blood immunity.

Mr. H. BETHAM ROBINSON read a paper on a case of Extra-peritoneal Rupture of the Bladder without Fracture of the Pelvis, and the meeting concluded with a paper by Mr. L. A. DUNN on a case of Retrograde Enteric Intussusception.

CLINICAL SECTION.

Exhibition of Cases.

A REPORT of Major Leonard Rogers's paper on the treatment of cholera among Europeans at Palermo, read at a meeting of this section on Nov. 10th, and the discussion thereon, were published in THE LANCET of Nov. 18th. At the same meeting many cases were exhibited, details of which are given below.

Dr. HERBERT P. HAWKINS showed a case of Enlarged Spleen with Recurring Hæmatemesis. The patient was a girl aged 9. She was said to have been pale and delicate from her birth. At the age of 4 she suddenly vomited half a pint of blood without pain and without any previous symptoms pointing to gastric disease. She was admitted into the Belgrave Hospital for Children and apparently soon recovered. At the age of 6 she had a second hæmatemesis, equally sudden, and she was said to have vomited a pint of blood. This was followed by melæna for several days. It was not certain, but it was probable, that this attack was accompanied by some pain in the epigastrium. She recovered in about six weeks. Early in 1910, at the age of 8, she began to have frequent attacks of pain "in the stomach and around the heart." Crops of small purpuric spots appeared on the chest, and the mother stated that she was easily bruised. On one occasion there was epistaxis. She was becoming pale and weak, and on admission into St. Thomas's Hospital in April of that year melæna was observed on several days in succession. The spleen projected 2½ inches below the costal margin and it was indurated. Red cells were 2,425,000, with a colour index of 0·7; leucocytes were 3700. Three normoblasts and five megaloblasts were seen. Polychromatophilia was marked. The coagulation time was 2·5 seconds. There was no other sign of disease beyond hæmic murmurs. After a month of treatment with arsenic the red cells were 3,437,000, with a colour index of 0·6. She remained fairly well, though always pale, till July 27th, 1911, when she suddenly vomited a pint of blood. For six weeks before this she had complained from time to time of abdominal pain just above the umbilicus. A few hours later there was further hæmatemesis, and melæna followed for several days. The spleen was enlarged and hard as before. Red cells were 2,200,000, colour index 0·5, leucocytes 2980, with no change in relative proportions; two normoblasts, but no megaloblasts seen. For 14 days there was pyrexia, maxima being 101° to 102° F. Under the use of arsenic the condition of the blood had slowly improved. The red cell count was now 4,328,000, colour index 0·8, leucocytes 3600. She was fairly well; she took food freely without any discomfort, but she was not gaining weight. The liver was just palpable, but it was within the limits of health. The pulse was seldom under 100, and the urine occasionally contained a trace of albumin. The spleen moved freely with respiration, and the question was whether the condition of the blood and the history of the illness justified its excision.

Dr. W. ESSEX WYNTER and Mr. JOHN MURRAY showed a case of Toxic Cirrhosis, with Spleno-portal Thrombosis and Ascites (Banti's Disease), treated by femoral drainage. The patient was a female aged 44. Eight years back, during pregnancy, while moving some furniture, she felt something give way in the left hypochondrium. Subsequent to delivery a lump was felt in this situation, and three months afterwards there was enlargement of the abdomen; three years ago, in similar circumstances, the abdomen was again distended. For three months before admission this distension had been increasing so as to cause difficulty in walking and breathing, with pain when lying on the left side, and œdema of legs. Diarrhœa had been constant. There was well-marked ascites, and the spleen descended to the level of the umbilicus. The diaphragm was pushed up, displacing the heart and causing some collapse of the bases of the lungs. The liver was small. On March 10th, 1911, 21 pints of serum were removed by paracentesis. It had a specific gravity of 1018 and contained 40 gr. per litre of coagulable protein and traces of mucin, but no reducing substance or cells. On March 24th, 28 pints were removed by paracentesis. On the 28th Mr. Murray opened the femoral ring through a semilunar incision in Scarpa's triangle. A small opening was made above Poupart's ligament to enable the peritoneum to be pushed through. This was then divided and stitched to the sides of the ring. A considerable amount of fluid escaped, but the abdomen was not completely emptied. The incisions were closely sutured, and healed in a few days. On account of the rapid formation of fluid causing tension in the femoral wound, paracentesis was twice performed in the surgical ward—May 5th, 23 pints, 16 oz.; May 23rd, 10 pints, 12 oz. She was discharged on May 26th. During September, owing to distension of the upper femoral region by gravitation of fluid, the scar again gave way, leaking slightly; owing to apprehension of possible peritoneal sepsis the patient was readmitted and fitted with an elastic support. While lying up the ascites returned and 16 pints were removed on

Sept. 29th before leaving. This was the first tapping since May 23rd (four months).

Dr. WYNTER also showed a male patient, aged 54 years, who was exhibited to the Fellows on Dec. 13th, 1907, as an example of Ascites due to Cirrhosis Hepatis, cured by permanent drainage through the femoral ring. This man, during the four years which had elapsed since the operation, had had no further ascites. There was slight yielding of the abdominal wall at the site of the scar, but this had caused no inconvenience.

Dr. WYNTER also showed a male patient, aged 50 years, who was operated upon for Ascites associated with Cirrhosis of the Liver in 1908, an additional precaution against premature closure of the femoral opening being the insertion of a decalcified bone tube. The patient had been at work for three years feeling quite well. At the present time there was some free fluid in the peritoneal cavity, and a dilated tortuous saphena vein indicated some obstruction at the site of operation.

Dr. N. S. FINZI showed a case of a large Malignant Growth of the Cheek which had disappeared under radium treatment. The patient was a female aged 48 years. She had been previously shown at the Laryngological Section in June. Since the age of 7 she had had a soft and painless swelling growing from the mucous membrane of the cheek. In May, 1910, this became painful, and a month or so afterwards enlarged, and continued to increase in size until it was removed widely in November, 1910. All seemed satisfactory until Dec. 19th, when there was a sudden rapid swelling in the cheek. This increased rapidly and was incised a few days later and a drop or two of thin pus obtained; nevertheless, the growth continued to increase rapidly. Early in the year there was an enormous swelling in the cheek of about the size of a Jaffa orange, slightly moveable, but with considerable œdema round it. At one spot it seemed on the point of bursting externally, as there was a small fluctuating area covered by extremely thin skin. No definite glands were felt, but the œdema, especially in the pre-auricular region, might have obscured these. From Jan. 3rd to 7th Dr. Finzi applied radium bromide, 105 mgr., in two tubes, one surrounded by platinum 1½ mm. thick, and the other by lead the same thickness, inside the tumour for 69 hours, and on lint outside the skin in two situations for 12 hours each. On Feb. 2nd the tumour had shrunk considerably, but there was a pre-auricular gland to be felt. This was excised and 100 mgr. of radium bromide with a filter of 2·5 mm. platinum was inserted into the wound for nine hours. On Feb. 23rd there were still a few nodules in the cheek; 205 mgr. of radium bromide were applied on lint externally for 30 hours and internally for nine hours. On May 11th prophylactic treatment was given with 205 mgr. radium bromide 34 hours in all. The patient now seemed quite well and the scar had gradually and continuously softened. Dr. Finzi said that it might be remarked that there was never any sign of sloughing of the growth after the treatment, but it simply gradually became absorbed, leaving in its place a depression and a scar. Sections were shown of the original growth and of the gland which was removed. The nature of the growth was either that of a glandular carcinoma or of an endothelioma.

Dr. REGINALD H. MILLER showed a case of Hæmochromatosis with Diabetes. The patient was a man, aged 38, who had noticed darkening of the skin for 18 years, but remained in good health until five months ago, when he began to waste and to suffer from thirst. The pigmentation began on the left shoulder, where the patient carried his bag of tools. It was now universal and was best marked on the face (which was leaden-hued), forearms, and legs. A recent scar on the skin was deeply pigmented. No part of the skin was normal in colour. In addition to the bronzing there were innumerable small darker spots resembling freckles. The scalp was pigmented, but not so deeply as the face. Axillary hair had disappeared, but pubic hair was present. The urine contained much sugar (6 to 10 per cent.) and acetone; from 100 to 150 ounces were passed daily. The glycosuria was little controlled by diet. The blood count shows—red cells, 4,700,000; white cells, 7900; hæmoglobin, 92 per cent. The mononuclear cells were proportionately increased. The liver was enlarged to the umbilical level, firm, and not tender. There were no symptoms of hepatic cirrhosis, and the patient had only suffered from very occasional attacks of mild indigestion throughout the course of the illness.

Mr. W. SAMPSON HANDLEY showed a case of Ivory Exostosis of the Frontal Sinus. The patient was a man, aged 35, who had noticed a lump growing on the inner side of his right eye for about three years. It had not given him any pain. At the operation an incision was made along the inner half of the eyebrow, inclining downwards towards the inner canthus. The exostosis was continuous with the frontal bone at the inner wall of the sinus, and here its base was divided with a chisel and removed. There was free bleeding, and air bubbled up from the bottom of the cavity, showing that it communicated with the nose. The cavity was packed and allowed to heal by granulation. The patient had suffered from bilateral nasal polypi for some years prior to the development of the osteoma. Five years ago the patient had three "black eyes" on the right side in quick succession, and thought that there had been some swelling ever since.—Mr. T. JEFFERSON FAULDER described a case and exhibited the exostosis removed.

Dr. NORMAN DALTON showed a case of Malignant Anæmia, Hæmolytic Type. The patient was a female, aged 59, who was admitted to King's College Hospital on Sept. 28th, 1907. The case seemed to be one of those rare instances of gastric cancer in which hæmolysis occurs, thus simulating the true pernicious anæmia. By Oct. 7th she seemed to be dying, was extremely prostrate and delirious, with a glazed tongue. She was now put on bismuth mixture and gradually improved. By Oct. 29th the red discs had gone up to 1,028,000, the colour index being 2. Vomiting ceased. She was able to leave the hospital on Nov. 22nd, 1907, greatly improved. A lump of doubtful nature noticed in September could not now be felt in the epigastrium. She was re-admitted on May 4th, 1908. She was extremely prostrate, vomiting, œdema of the feet, retinal hæmorrhages, &c. The epigastric lump could again be felt. She was put on liq. arsenicalis, ♏ iv., three times a day, but became worse, the vomiting being constant and delirium setting in. The red discs were 624,000, the colour index being 1·5: there was great leucopenia with relative excess of lymphocytes, megaloblasts, normoblasts. She was put on bismuth mixture instead of arsenic, and improved. On June 10th the red discs were 1,764,000, and the colour index was 1·8; there were no nucleated red discs. The spleen had never been found enlarged. She was well enough to leave the hospital on June 13th, and for two years she was able to get about at home and to do some house work. At Christmas, 1910, the asthenia and vomiting recurred, and she was readmitted to the hospital on July 17th, 1911. The red discs were 976,000, but the colour index was now just below normal. Abnormal red corpuscles were found. The abdomen was now full with a little ascites, and the liver and (?) the spleen became enlarged. She was very ill for a few days—viz., vomiting, glazed tongue, delirium, &c.—but improved under bismuth. By August 29th the red discs had gone up to 2,092,000, the colour index being 1, and no abnormal reds being found. On Sept. 21st the red discs were 3,280,000, and she is now really very well. The points about the case were that the toxins which cause the hæmolysis appeared to come from the stomach, because when she was ill the vomiting was such a prominent symptom, and bismuth brought her round, while arsenic made her worse. When, however, the gastric symptoms ceased she could take arsenic with advantage. It would seem as if the arsenic could not exert a favourable influence until the gastric irritation had been subdued. The original idea of cancer of the stomach must be abandoned after four years.

Dr. LEONARD WILLIAMS showed a case of Nocturnal Enuresis treated with Thyroid Gland. This patient's case was reported in THE LANCET of May 1st, 1909, in an article entitled "Adenoids, Nocturnal Incontinence, and the Thyroid Gland," as follows: "The patient, a girl, aged 11 years, was first seen on Feb. 2nd, 1909. She had wetted her bed every night since birth. For the last few years she had, in consequence, slept on straw. She was dull and apathetic, but not stupid. She was thirsty but her appetite was poor. The patient was not undersized and her weight was 5 st. 1 lb. The tonsils were somewhat enlarged, but there were no adenoids or nasal obstruction. The temperature was 99° F. in the mouth. One and a half grains of thyroid extract, three times a day, were ordered. Feb. 9th: The patient had missed wetting her bed for the last three nights—the first in her life. The same dose of thyroid extract was ordered. 16th: On three successive nights the bed had not been wetted. The

dose of thyroid extract was increased to 2½ grains three times a day. 23rd: No enuresis had occurred during the week. Thyroid extract was ordered as before. March 2nd: No enuresis. 9th: No enuresis. 12th: No enuresis." On March 12th, although there had been no enuresis, the patient complained of pain in the left arm, and on examination the elbow proved to be swollen and tender. She did not come to the hospital again until March 26th, and was consequently without medicine for a week. The bed had been wetted once, the night before her return. The dose of thyroid was reduced, and a mixture was ordered containing calcium iodide and arsenic. On April 2nd there had been no enuresis; the thyroid was stopped, but the mixture continued. On April 16th the bed had been wetted four times in 14 days; the thyroid was repeated. April 23rd: Enuresis had occurred once. April 30th: No enuresis. The patient remained quite free from enuresis from April 30th to August 11th. She was coming regularly to the hospital during that time, and was taking 1½ gr. of thyroid extract. The notes show that during that period there had been complaints of pains in the joints, especially the elbows and knees. From August 11th to Oct. 6th she remained away from the hospital. Having been given a supply sufficient for a month only, she had thus been without treatment for more than three weeks. On reporting herself at the end of that period she stated that she had wetted her bed three times during the previous week and once during the current week. From this date (Oct. 6th, 1909), under regular thyroid medication, there was, up to March 8th, 1910, no enuresis. She then disappeared from the out-patient room. During this time there had been several complaints of joint troubles. Early in January, 1911, I found her in the wards, under the care of Dr. W. Langdon Brown, who had been treating her for a typical attack of acute articular rheumatism, which had affected her mitral valve. There had been no urinary difficulties in the course of the attack, but the enuresis returned during convalescence. It was controlled, though tardily, by thyroid medication, continuing with considerable remissions until April 25th. On May 26th, 1911, she came to the hospital with a definite attack of left-sided hemichorea, which rapidly yielded to large doses of arsenic. In August she began menstruating; the periods have been regular and painless, but unduly profuse. Nov. 7th: involuntary movements returned last week. The mother of the patient was interesting as a case of pseudo-obesity, who was unable to tolerate the smallest dose of thyroid.

Mr. V. WARREN LOW showed a case of Lipoma of the Tongue. The patient was a man, aged 59 years, who had noticed the swelling on his tongue for eight years. It had been of gradual onset and had increased in size slowly. There was no pain, and only inconvenience owing to the size of the organ. There was a lobulated tumour on the right lateral aspect of the tongue extending for two-thirds of its length. The mucous membrane over the tumour was smooth, and through it could be distinctly seen the underlying lobules of fat. There was no infiltration of the tongue, which could be readily and easily protruded.

MEDICAL SOCIETY OF LONDON.

Differential Diagnosis of Syphilis and Parasyphilis of the Nervous System.

MEETINGS of this society were held on Nov. 13th and 20th, Dr. J. MITCHELL BRUCE being in the chair.

Dr. F. W. MOTT opened a discussion on the Differential Diagnosis of Syphilis and Parasyphilis of the Nervous System, which was published in last week's issue of THE LANCET, p. 1392.

Sir DAVID FERRIER said that parasyphilitic affections of the nervous system—by which term he understood tabetic affections, whether spinal (locomotor ataxy), cerebral (general paralysis), or cerebro-spinal—formed a separate class, and when all or most of the cardinal symptoms were present were readily distinguishable from syphilitic affections proper. The term parasyphilis had a recognised significance, and every day strengthened the evidence that all tabetic affections were primarily of syphilitic origin, and that whatever else might be coöperative syphilis, hereditary or acquired, was a *sine quâ non* in their causation. But while parasyphilitic affections, when fully developed, were easily distinguishable from cerebro-spinal syphilis, doubts might be entertained by even the most experienced observers when the affections were in their incipient stage or when the manifestations were imperfect, irregular, or complicated by other symptoms due to syphilis or not, as the case might be. If he were to specify one symptom or sign above all others characteristic or pathognomonic of parasyphilis, he would without hesitation say the Argyll Robertson pupil, or condition termed reflex iridoplegia. That was practically always a sign of parasyphilis. Occasionally all symptoms might be so equivocal that they gladly availed themselves of the valuable aids to diagnosis which had been in recent times added to their resources in biochemical and cytological examination of the blood and cerebro-spinal fluid. Whatever might be the correct interpretation of the Wassermann reaction—and he thought the balance of evidence was against it being a specific immune reaction—there was, he thought, little doubt that, in its clinical setting, it was absolutely pathognomonic of antecedent syphilitic infection. It was, however, as Much termed it, a constitutional and not a symptomatic reaction. In cerebro-spinal syphilis it was obtained only in the serum, whereas in general paralysis it occurred with equal frequency in the cerebro-spinal fluid, and with almost equal frequency in that of spinal tabes. Those facts were of inestimable importance, and a positive Wassermann reaction of the cerebro-spinal fluid in a doubtful case would be quite sufficient to dispel all doubts as to the true nature of the case. There was one point of difference between general paralysis and cortical syphilis, which he had been in the habit of demonstrating at his hospital clinics for a great many years. It was that he had never found a general paralytic, at whatever stage of his disease, complain of or evince signs of pain on deep pressure or percussion on any part of his head; whereas in cortical syphilis, even when the patient had made no complaint of spontaneous headache, it was practically the invariable rule that pain, often obviously severe, could be elicited by deep pressure over the seat of lesion.

Dr. G. H. SAVAGE said that years ago he had been told that he was teaching wrongly when he said that general paralytics rarely complained of tenderness about the head or of headaches. He could only answer that it was very exceptional for him to meet with such a case. It was very common to meet people who were suffering from parasyphilitic trouble and other similar troubles, and who had headaches. Cases of parasyphilis and cerebral syphilis almost invariably slept badly. But the general paralytic, except in the stage of maniacal excitement, often slept very well indeed and did not complain of sleeplessness.

Dr. RISIEN RUSSELL said that he was in complete accord with Dr. Mott in regard to the failure of anti-syphilitic treatment in general paralysis, but he was fully convinced of its efficacy in tabes, and considered that no patient in the early stages of that disease should be allowed to go untreated by mercury administered by inunction or injection. Dr. Russell was glad that emphasis had been laid on the importance of differentiating neurasthenia from the affections that were under discussion. While failure of the pupil to react to light was all-important as proving the organic nature of the disease, the same could not be said of mere inequality of the pupils, for it was no uncommon thing to meet with unequal pupils in neurasthenia without its meaning that an organic basis existed to account for the neurasthenic symptoms. That the headache of brain syphilis was usually more severe than that ordinarily met with in neurasthenia there could be no doubt, but it could not be said that, although other cephalic sensations occurred in neurasthenia, those did not include headache, for the reason that true headache was a common symptom in the affection, and it might even be characterised as severe in some cases. He could most cordially endorse all that had been said in regard to the value of the Wassermann test and the examination of the cerebro-spinal fluid. Contrary to what he understood Dr. Mott to say, however, he had met with cases in which the Wassermann reaction from the cerebro-spinal fluid had been said to be positive when the blood had given a negative reaction. He had seen both ankle clonus and the extensor type of plantar reflex sufficiently often in general paralysis to rob those signs of the value with which they had been credited in the diagnosis of brain syphilis as opposed to general

paralysis. Excepting in cases of tabes-paralysis he was not in the habit of associating oculo-motor paralysis or gross paralysis of any cranial nerve with general paralysis, but had always regarded any such palsies as in favour of brain syphilis in contra-distinction to general paralysis. It was gratifying to hear such a definite pronouncement in regard to the value of the Argyll Robertson pupil in support of the parasyphilitic affections, for it accorded with his own experience.

Dr. E. FARQUHAR BUZZARD said that he believed he was correct in saying that Dr. Mott regarded parasyphilis as an abiotrophic process which, although it followed syphilis, was not in itself syphilitic, and did not depend for its progress upon the activity of the syphilitic virus. He entirely agreed with Dr. Mott that the pathological process underlying tabes was not a gross structural change comparable with that which they saw in the inflammatory lesions of syphilis, but he could not help looking upon it as one which was due to an active intoxication rather than as the expression of a primary neuronic decay. They were told—and he agreed with the statement—that the majority of tabetics gave a positive serum reaction. At the same time, Dr. Mott stated that the latter was an indication that the syphilitic virus was *still* active. If both those observations were reliable, they were certainly reconcilable with the view that tabes was the result of an active toxic process. On the whole, he found it *difficult* to regard the irritative phenomena of tabes as due to the degeneration of neurons prior to their death and loss of function. Many of them could be modified or averted by energetic antisyphilitic treatment, and in his opinion were the direct result of an active toxic agent. After all, the so-called parasyphilitic diseases were really the only syphilitic diseases of the nervous system; cerebro-spinal syphilis was not syphilis of the nervous system, but syphilis of its supporting and nutrient tissues. He agreed with all that Dr. Mott had said with regard to the value of the Wassermann reaction of the blood and of the cerebro-spinal fluid, but he had learnt to be careful not to attach too much importance to a negative result. They had heard much of the value of the Wassermann reaction in tabes. They had heard, too, of the Argyll Robertson pupil, of the absent tendon jerks, of Romberg's sign, and so on, but the ordinary physician, like himself (Dr. Buzzard), needed to give an opinion without constant resort to laboratory tests, and he could not shrink from diagnosing tabes sometimes even when Argyll Robertson pupils were absent or knee-jerks were present. Too little attention was paid habitually to the sensory phenomena of tabes, which on the whole were as reliable a guide as any other to a correct conclusion if their characteristics were appreciated. In view of the test-tube tendencies of the present time he did not think one could urge too strongly the importance of teaching medical students all there was to know about ordinary bedside methods of examination.

Mr. A. FLEMING said that the uses of the Wassermann reaction in nervous diseases were: (1) by examination of the serum to see if the patient had syphilis; (2) by examination of the spinal fluid to detect parasyphilitic affections, and especially general paralysis; and (3) to reassure the patient who had been cured, and so remove the dread of future trouble.

Major H. C. FRENCH, R.A.M.C., wrote that the number of brain and spinal syphilis cases in the army was very small in comparison with the large number of cases of syphilis. In his experience it was well under 3 per cent. as regards mixed methods, and not more than 1 or 2 per cent. in cases thoroughly treated by mercurial inunction and baths in the primary and early secondary stages. Two facts contributed to the relative infrequency in the army: first, the judicious early use of mercury; secondly, the fact that soldiers left the service, as a rule, under 40 years of age. In cases of cerebral or spinal syphilis which he had met with in the army it was the rule for them to have either been overlooked and entirely untreated in the initial stages of the disease, or they had frequently received such scanty treatment as to be scarcely worth the name. Dr. Lévy-Bing had informed him (Major French) a month ago in Paris that he had given over 500 intravenous and intramuscular injections of salvarsan. He had never succeeded in aborting syphilis even after four weekly doses in the primary stage. He found that the Wassermann reaction became negative in many cases, but it was the rule for it to become positive within two months. After six or seven months he frequently saw nervous manifestations develop, and he mentioned two recent cases of meningitis, facial paralysis, and extensive skin eruptions. The general opinion was that intravenous injections of salvarsan were therapeutically better than intramuscular, but that mercury should be administered for three years was the opinion commonly held by those who had extensively tried both drugs.

Mr. HUGH W. BAYLY said that he wished to place before them the results that he had obtained with the Wassermann reaction during the last year at the National Hospital, Queen-square. He had examined 11 cerebro-spinal fluids, and of those four were positive. He saw, however, from Dr. Candler's interesting paper in THE LANCET of Nov. 11th that he had been using too little cerebro-spinal fluid which might account for his low proportion of positives. With regard to the blood serum, of 33 cases diagnosed as tabes 13 were strongly positive, 9 positive, 1 doubtful, and 10 negative. That gave 70 per cent. of positives. Of 5 cases of doubtful diagnosis in which tabes was queried 4 were negative and only 1 positive. Of 17 cases diagnosed as general paralysis of the insane, 12 were strongly positive, 3 positive, and 2 negative = 88 per cent. positive. Of 8 cases in which general paralysis of the insane was queried, but not actually diagnosed, 3 were positive and 5 negative. Of 21 cases in which cerebral tumour was suspected only 3 (14 per cent.) were positive reactions. Of 18 cases of paraplegia examined only 4 (22 per cent.) were positive. Of 11 cases of hemiplegia only 3 (27 per cent.) were positive. Of 13 cases of pachymeningitis only 4 were positive. Of 10 cases of disseminated sclerosis 2 were positive and 8 negative. Eight cases of epilepsy and 4 cases diagnosed as cerebral thrombosis were all negative. Of 3 cases of primary optic atrophy examined, all three were positive. Purves Stewart had stated that the lymphocytosis of tabes and general paralysis of the insane was more marked than in any other form of organic nervous disease. Syphilis by itself, unless there be an active syphilitic lesion of the central nervous system, produced little or no excess of lymphocytes in the cerebro-spinal fluid. F. Plaut says that cellular increase may be found in secondary or tertiary stages (even though only latent) without any syphilitic manifestation in the central nervous system. The number of lymphocytes may reach a great height, up to 400, without producing a positive Wassermann reaction in the cerebro-spinal fluid, and *vice versâ* the intensity of the Wassermann reaction of cerebro-spinal fluid is in no relation to the cell contents, one case with a very strong Wassermann reaction showing 17 cells, and another with a very weak Wassermann showing 245 per cubic millimetre. There was also no relation between the strength of the blood Wassermann and the cellular content of the cerebro-spinal fluid. Dr. Mott had obtained a positive Wassermann reaction in every case of tabes and general paralysis of the insane in the blood, and considered that the amount of lymphocytosis in the cerebro-spinal fluid was an index of the activity of the disease. Dr. Mott found that in tabes and general paralysis of the insane antisyphilitic treatment had no effect on the lymphocytosis, so he (Mr. Bayly) imagined that it would only be in syphilitic meningitis that that effect was produced. Candler considered that an excess of lymphocytoses in the cerebro-spinal fluid indicated organic disease, but not necessarily either syphilis or parasyphilis. It was difficult to bring the observations of those four authorities into line. He (Mr. Bayly) would ask Dr. Mott whether he would consider a diminishing Wassermann in the blood or a diminishing lymphocyte content in the cerebro-spinal fluid the more valuable indication of improvement and reaction to treatment.

Dr. WILFRED HARRIS said he had hoped that Dr. Mott would have said something about a special neuro-toxin in connexion with the development of general paralysis and tabes; there were so many instances of individuals being infected from the same source and having general paralysis or tabes. There was one instance of as many as seven people being infected by one blow-pipe for blowing gas, and five developing general paralysis of the insane or tabes. The facts concerning conjugal tabes and conjugal general paralysis pointed in the same direction. With regard to injury, he had twice seen general paralysis follow so closely upon injury of the head that he was inclined to regard it as a determining factor in the disease.

Lieutenant-Colonel A. DE C. SCANLAN, R.A.M.C. (retired),

expressed his entire disagreement with the view of Sir David Ferrier that syphilis was a *sine quâ non* in tabes; he differed also from Dr. Mott that syphilis was practically the only cause of that disease. He had seen a considerable amount of syphilis in the army, but he had seen only one case of tabes in the army, though several cases had come under his notice outside the army, and in those he had found no signs of syphilis whatever. His opinion was that tabes was due to a toxæmia and that syphilis was only one of the causative factors.

Dr. H. CORNER remarked that when he was at Bethlem Hospital many years ago he took a great deal of interest in the question of general paralysis of the insane in its connexion with syphilis, and he would like to know whether Dr. Mott looked upon syphilis as the only cause of general paralysis. His opinion was that something beyond syphilis was required in order to produce general paralysis, and that syphilis was a predisposing cause producing a low form of inflammation throughout the body, and there was a tendency to proliferation of cells and a tendency to a cirrhotic condition later on. The progressive character of general paralysis and the non-progressive character of other syphilitic lesions was a fact which needed explanation.

Dr. MOTT, in reply, thanked all those who had taken part in the discussion. He said that many cases of tabes under his own care had benefited a good deal by mercurial treatment. He was doubtful whether mercury did much good for general paralysis of the insane. Many blood examinations of the cerebro-spinal fluid and of the blood had been done at Claybury, and invariably in general paralysis there was a reaction with the blood serum when there was a reaction in the cerebro-spinal fluid. But he had heard of cases in which the cerebro-spinal fluid gave the reaction and the blood did not, and therefore he would not be too dogmatic on the point. He did not consider that the Wassermann reaction should be looked upon as absolutely infallible. He did not say one could not get a positive Wassermann in cerebral syphilis, but if the cerebro-spinal fluid gave a positive reaction it was 5 to 1 that it was parasyphilitic and not syphilitic.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Some Aspects of High Blood Pressure.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Nov. 10th, Mr. H. LITTLEWOOD, the President, being in the chair.

Dr. A. MANTLE read a paper on Some Aspects of High Blood Pressure Requiring Special Consideration in Treatment. He said: It is an interesting fact that it is to two members of this society, Dr. George Oliver and Sir T. Clifford Allbutt, the profession owe so much for pressing home the importance of blood-pressure observations being made as they now are in almost all consulting rooms and medical wards. In normal man the average level of blood pressure is maintained with great constancy, and of all the parts of the vascular system the abdominal vessels innervated by the splanchnic nerves have by far the greatest effect on general blood pressure, and Janeway says that an abnormally high pressure cannot exist permanently unless there has been some damage to the regulating power of the visceral circulation. The most common source of the poison disturbing the visceral circulation is from the alimentary canal when the toxic products of decomposition, the result of over-indulgence, become absorbed. Lead and alcohol, which also bring about a disturbance of metabolism, act in the same way, and so probably does sepsis. The result of these disturbances is the absorption of pressure toxins and a rise in the blood pressure. The influence of prolonged worry through the nervous system in bringing about visceral circulatory changes, as also that of external temperature—exposure—in the hypersensitive, is great, and may lead to high blood pressure and arterio-sclerosis if the defences of the body are found weak, particularly those of the liver and kidney. High blood pressure may be *temporarily* high or *permanently* so. A temporarily high pressure may be due to a disordered metabolism, and more often it is met with in the neurotic subject, and too much attention should not be paid to such observations. It is the permanently high pressure which gives us anxiety, and the effects of such may be very far-reaching, for the increased resistance in the vessels and left ventricle which has to be overcome soon leads to a thickening of the muscular fibre and eventually to fibrotic changes. Arterio-sclerosis when developed may not affect the whole arterial tree, but may be local. In the latter cases with an unequal distribution of sclerosis there may be no appreciable rise in blood pressure, although considerable disease is very apparent in some of the superficial vessels. Hyperpiesis is a name given by Sir T. Clifford Allbutt to a class of case in which we have a high blood pressure with or without cardiac hypertrophy and symptoms (possibly covering years) referable to a functional disturbance of the liver and bowels. It occurs in the middle-aged, who show no symptoms of arterio-sclerosis and with no evidence of nephritis. Some of these cases get better if detected early. They are frequently associated with chronic constipation and are due to toxins absorbed from the bowel having pressure properties. The treatment of super-pressure has been too much confined to drugs of the vaso-dilator type and to iodides. If there is a loss of balance between the peripheral and splanchnic circulations we want to restore it and not allow too much blood in the organs of the splanchnic area with too little in the skin reservoir, for this must mean congestion of the viscera involved. This can be relieved by judicious purgation, and best probably by mercury in the form of calomel or blue pill and saline purgatives. The skin must also be kept active by attracting blood to the systemic periphery, and no doubt the *régime* and balneological treatment of a good spa are very helpful in cases of supernormal pressure. It being proved that purin bodies and alcohol keep up the pressure, a very regulated intake must be insisted upon with a diminution of red meats and salt. Supernormal pressure is not in itself a primary condition, and we must look for the causes of it. A word of warning must be given to the enthusiast who, seeing the mercury of the manometer reach the top of the tube, determines to have it down at any cost, for he forgets that owing to the gradual increase of blood pressure each individual readjusts his cardio-vascular physiology to compensate this, and the physiological limit is not now 130 to 140 mm. Hg, but may be 220 mm., and to reduce pressure below this new physiological limit is not only not indicated but bad treatment. In other cases it is noticed that with the development of symptoms from the heart the pressure falls, and then it is our duty to raise it with digitalis or strophanthus, and vaso-dilators must on no account be given. It is important to remember that high blood pressure does not mean in all cases arterio-sclerosis and nephritis, but is a condition which is not infrequently amenable to treatment.

Dr. J. H. FRYER showed a man suffering from Diffuse Scleroderma. The symptoms had started some 12 months before with arthritic manifestations, and the condition was diagnosed by several observers as a rheumatoid one. The arthritic pains were due to the thickening and contraction of the tissues round the joints. So marked was this that fissuring of the skin occurred over many of the smaller joints of the hand. There was also much pigmentation. The condition was gradually passing off, apparently having been uninfluenced by any form of treatment.

Mr. H. COLLINSON showed a girl from whom a large Retro-peritoneal Tumour had been removed. The tumour occupied the whole of the left side of the abdomen and the third part of the duodenum passed across it. In removing the tumour the duodenum was torn, and owing to difficulty in repairing the rent three inches of the duodenum were removed, the proximal end was closed completely, and the jejunum anastomosed with the stomach. The patient had recovered without any complication and was taking ordinary food without inconvenience.

Dr. T. WARDROP GRIFFITH referred to some cases that had recently been under his care which presented the physical sign known as the "third sound" of the heart. The association of this with the presence of an extra wave in the jugular pulse was discussed, and tracings were shown from the cases in which this wave was well seen. The extra wave in question was that described by Hirschfelder and by A. G. Gibson, and followed on the fall of the so-called ventricular wave of Mackenzie. The summit of this ventricular wave was usually regarded as indicating the end of ventricular systole and the consequent opening of the auriculo-ventricular valves, and the extra wave had been regarded as being due to the initial rush of blood into the

ventricles leading to a temporary closure of the auriculo-ventricular valves, a closure which it was thought was the cause of the extra sound in question. It was believed that the extra sound was due to the closure of the mitral rather than the tricuspid valve, for the blood pressure attained to a much higher level in the left auricle than in the right, being driven into the left by the contraction of the right ventricle. The extra wave in the jugular pulse was, of course, an indication of what was going on in the right side of the heart, and indicated a temporary closure of the tricuspid valve during the early part of the ventricular diastole just after the initial rush of the blood from the auricle, and it might be that this closure contributed to the sound under discussion. The importance of recognising the sound was commented on, and especially its distinction, which was sometimes difficult from the early and short diastolic bruit of mitral stenosis. The wave of Hirschfelder and Gibson was often seen in jugular tracings in patients who did not present the third sound; this was natural, the sound was a feeble one at best, and its occurrence meant a somewhat vigorous closure of the auriculo-ventricular valves.

Dr. G. W. WATSON showed a specimen of Acute Vegetative Endarteritis of the Aortic Arch from a man, aged 59, who gave a definite history of syphilis. Death occurred from malignant disease of the transverse colon. In addition there was found an active tuberculosis of the lungs.

Dr. ALEXANDER SHARP showed a case of Gumma of Highmore's Antrum, with subsequent destructive lesion in the nose, causing necrosis of the inferior turbinal, nasal antral wall, part of the hard palate, and posterior part of the septum. There had been immediate response to "606."

Mr. B. G. A. MOYNIHAN showed a specimen of Diverticulitis of the Sigmoid. The condition had given rise to acute symptoms in the left lumbar region, and an abscess had been opened with a fæcal fistula as the result, when the case came under his care. Mr. Moynihan then performed a second operation, resecting the diseased portion of the gut, with complete recovery.

Dr. J. B. HELLIER showed a case of Sarcoma Uteri, with sarcoma of ovary, right pyosalpinx and appendicitis, and abscess in omentum. The affected parts were removed and good recovery made.

Dr. C. OLDFIELD showed a case of Post-abortion Tetanus in which recovery had taken place after the use of anti tetanic serum.

The PRESIDENT showed a patient on whom he had successfully operated for Ruptured Liver. The patient, a boy aged 12 years, fell down a hole 4 feet deep, and injured his abdomen by striking it against a stone. He was operated on about six hours after the accident on July 28th last. On opening the abdomen it was found full of blood, and a rupture on the upper surface of the right lobe of the liver, about 3 inches in length, which was freely bleeding. As the rupture was far back and could not be brought to the surface, the round ligament and part of the falciform ligaments were divided; this made it possible to bring the liver easily forward into the wound. The rupture was closed by six deep No. 5 catgut sutures. The patient was very collapsed, and he was infused with three pints of saline solution. He made a good recovery.

Cases and specimens were also shown by Dr. A. G. BARRS, Mr. G. CONSTABLE HAYES, Mr. W. H. HOOTON, Dr. M. J. STEWART, and Dr. W. W. ADAMSON.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.

Pulmonary Gangrene, with Operation and Recovery.—Mycotic Infection.

A MEETING of this society was held at the Royal Devon and Exeter Hospital on Nov. 10th, Mr. J. M. ACKLAND, the President, being in the chair.

Dr. W. GORDON reported a case of Pulmonary Gangrene, with Operation and Recovery. The patient, aged 35 years, had had an attack simulating influenza on August 25th, 1911, and was confined to bed for three days; after an interval of six days a relapse took place, with raised temperature and a complaint of great pain between the shoulders. He returned to bed with cough and expectoration, the latter becoming horribly offensive in 48 hours. On Sept. 30th Dr. Gordon first saw the patient in consultation with Dr. C. E. Stokes, when the outstanding features of the case were distressing attacks of paroxysmal cough, accompanied with the expectoration of intolerably offensive sputum of a greyish colour. Turpentine given four-hourly in 15-minim doses had exerted no apparent influence, and it was therefore decided to admit him to hospital for vaccine treatment, and if necessary operation. On admission the temperature was 100° F. and the patient was evidently losing weight. A patch of deficient resonance was found posteriorly in the right lung about its centre. There was no evidence of excavation. Dr. R. V. Solly punctured and withdrew a couple of drachms of grey fœtid fluid, and from this a Gram-negative bacillus was isolated and a vaccine prepared. Meanwhile turpentine was given by the mouth and continuous inhalations were employed. On the fourth day following admission 1,000,000 bacilli from the prepared vaccine were injected, but after an initial rise the temperature soon returned to its former level with no tendency to further reduction. At this juncture the sputum became blood-stained in addition to its extreme fœtor, and operation was decided upon. Dr. J. D. Harris, under local anæsthesia, opened a small cavity below the angle of the right scapula, and offensive material escaped showing here and there blackish pieces of lung tissue. Following upon operation the temperature fell and tended to remain lower, although irregular and intermittent. Vaccine treatment was now continued, 5,000,000 bacilli being injected on Oct. 9th. On the 11th the temperature was still 100° and both discharge and sputum were most offensive. Dr. Gordon then ordered one-drop doses of cyllin four-hourly, but although there was a fall of temperature no improvement could be detected locally. On the 15th a mixture containing iodoform gr. v., cyllin ℥ v., and olive oil ℥ ss. was injected into the lung along the drainage-tube. Beyond a sharp attack of coughing there were no disquieting symptoms following the injection, and this was repeated on the 19th. Rapid improvement followed, and on the 30th the tube was left out. Further vaccine injections of 10,000,000 and 20,000,000 bacilli were given on the 20th and 30th respectively. Beyond a small sinus discharging inoffensive pus the man was now almost well. In reviewing the case Dr. Gordon was doubtful that any curative effect could be referred to the vaccine treatment, but the beneficial influence of the cyllin and iodoform could hardly be disputed, the temperature falling to and remaining at normal shortly after the second injection. Dr. Gordon testified his gratitude both to Dr. Solly and Dr. Harris for their association in the case, and he congratulated Dr. Harris on the operative results in a type of case so often fatal under surgical interference.—Dr. HARRIS said that the accurate localisation of the house surgeon had rendered the operation speedy and effectual.—Dr. SOLLY emphasised the importance of isolating the organism by lung puncture. In this case the Gram-negative bacillus obtained appeared to be non-pathogenic. In his mind the origin of such a case would be pneumococcic, other organisms finding an entrance when hepatisation had given place to necrosis.

Dr. SOLLY read a paper on Mycotic Infection. In this he mainly followed the classification and description of the French authorities, and confined himself chiefly to the blastomycoses, or exascoses, and the sporotrichoses. As regarded the exascoses, he mentioned that De Beurmann and Gougerot used this word to include those blastomycoses which were well recognised and defined, while the word blastomycoses remained to cover the ill-defined and doubtful forms. I. The exascoses were divided into (*a*) the saccharomycoses, (*b*) the endomycoses, and (*c*) the zymonematoses. (*a*) The saccharomycoses were mostly rare conditions, but produced: (1) an infection of the mucous membrane resembling thrush; (2) a disseminated gummatoid mycosis with osteitis of tibia, and finally general septicæmia; and (3) tumour formation (due to saccharomyces tumefaciens) with in one case a lumbar abscess and meningitis. (*b*) The endomycoses. Common thrush due to endomyces albicans. This was occasionally generalised. Other endomycoses occurred due to allied endomyces. (*c*) Zymonematoses. The word had its derivation from the Greek, meaning yeast-filament. The organism occurred in the pus and tissues as a yeast cell, but filaments or mycelia also were produced in cultures. Examples of zymonematosis were: the zymonematosis of Gilchrist, or

blastomycosis (or oidiomycosis) American. This occurred mainly as a papillomatous dermatitis, but generalisation also occurred, with acneiform pustules, ecthymatous or serpiginous ulceration, subcutaneous gummatoid nodules, large or small abscesses, and invasion of bones and viscera, gastro-enteritis, nephritis, broncho-pneumonia, meningitis, with definite pyrexia, great emaciation, and marked deterioration of general health. The prognosis was very grave, but by early diagnosis and treatment by iodides, combined with surgical and electrical measures, recovery might be effected. The diagnosis was in most cases arrived at by a bacteriological examination. Bacterial infections (including tubercle) must first be excluded. Films should be treated in a wet state by 40 per cent. aqueous caustic potash, and cultures made on Sabouraud medium. A general diagnosis of exascoses might thus be made sufficient for the purpose of prognosis and treatment. II. Sporotrichosis. This disease was apparently very common in France, and would probably be found more frequently in England, when medical men were on the look out for it. A case had been recently published by Dr. Norman Walker and Dr. J. Ritchie of Edinburgh with a very complete description of its clinical and bacteriological aspect, and illustrated by beautiful plates. The prognosis certainly depended on the diagnosis. If treated by large doses of iodides, with local applications of preparations of iodine, a rapid cure ensued, but untreated or treated as a case of tuberculosis or syphilis it might last for years. The fungus in the pus and tissues occurred in a short oblong form, like a large short bacillus, but in cultures showed a felted mycelium, attached to which were numerous spores. There were various clinical forms of this disease. 1. The disseminated gummatoid form due to general dissemination of the fungus by the blood stream. This was divided into (*a*) the non-ulcerative form, where the gummata which might be disseminated all over the body, slowly softened, finally ending in a cup-shaped swelling with marked induration of edges, and containing a viscid fluid, and in which ulceration rarely resulted unless the abscess was incised; (*b*) the ulcerated form where ulceration was common and more rapid; and (*c*) the mixed form, with disseminated nodules, and also affections of mucous membranes, muscular tissue, synovial membranes, bones, eyes, testes, and various skin troubles, resembling eczema, acne, boils, pemphigus, lupus, &c. 2. The localised form with gummatous nodules starting as an initial lesion, or "chancre," and extending up the limb by means of the lymphatic vessels and so causing a succession of nodules, as in Dr. Norman Walker's case. A localised facial or cephalic form had also been described. Extra-cutaneous varieties also were found, particularly affections of the bucco-pharyngeal mucous membrane, either an acute anginous condition, possibly with false membrane, or in a papillomatous form. An acute febrile sporotrichosis also might arise, with successive exacerbations like an acute infectious disease. Each fresh attack of fever was signalised by a fresh eruption of gummata, and rigors, vomiting, epistaxis, and sleeplessness also occurred. In experimental sporotrichosis all these lesions were reproduced, and also general septicæmia, with lesions in kidneys, liver, suprarenals, and testes, and pneumonia, peritonitis, endocarditis, encephalitis, and meningitis. A hereditary sporotrichosis was also observed. Rats and mice were the best animals to experiment with. The commonest form of sporotrichosis was the sporotrichosis Beurmanni. The clinical diagnosis had to be made from syphilis, tuberculosis, leprosy, general lipomatosis, glanders, and osteomyelitis, coccic or tuberculous. One of the chief points to observe was the great number of lesions combined with the good general condition of the patient. The multiple, softening, gummatoid subcutaneous nodules were most characteristic. The bacteriological examination was simple. Direct examination of pus or other fluids was of little value. Culture at room temperature of material freely spread on Sabouraud's medium should be made, and a diagnosis might be made quickly by letting a drop of pus flow down the dry glass of the culture tube, and observing this day by day microscopically when mycelial threads might be observed, and finally the typical cultural form, with spores and felted mycelium. A more rapid diagnosis might be made by an agglutination test, using free spores obtained by filtering an emulsion of a culture in salt solution. Agglutination also occurred in cases of other mycoses, such as an endomycosis or actinomycosis, but in a lower dilution. Dr. Solly showed a culture of sporotrichosis Beurmanni and a section of an experimental lesion of the mouse, most kindly given him by Dr. Ritchie (obtained from his and Dr. Norman Walker's case). He also showed stained films and a living culture, observed microscopically growing on an agar hanging drop, of sporotrichosis from Dr. Ritchie's culture, and a microscopical Gram-stained specimen of an epithelial scale infected with mycelial threads from a case of extensive tinea circinata.

At the close of the proceedings a resolution was moved from the chair and carried unanimously congratulating Dr. C. J. Vlieland on his election as mayor of the city of Exeter for the ensuing year.

EDINBURGH OBSTETRICAL SOCIETY.

Valedictory Address.

A MEETING of this society was held on Nov. 8th, Dr. F. W. N. HAULTAIN, the President, being in the chair.

The PRESIDENT chose for his Valedictory Address the association of Sir James Young Simpson with the society, at this was the 100th anniversary of Simpson's birth. He joined the society in 1840, on the first occasion showing the external genitals of a female with central perineal tear. During his first year he made 18 communications, one of which was on the differential diagnosis of fibroid from ovarian tumours by auscultation and detection of the bruit. In 1841 he was elected president, a position he held for 16 consecutive years. During the next session he read a paper on the Diagnosis of Diseases of the Womb by the Employment of Uterine Bougies or Uterine Sounds, dilating on the use of the sound from a diagnostic and therapeutic aspect, and proposed the permanent retention of a sound in the form of an intra-uterine stem for displacements. With the inception of the sound a new era in gynæcology might be said to have arisen and pelvic diagnosis placed on a scientific basis. Though communicating many interesting papers it was not until Jan. 20th, 1847, that one of outstanding importance was given, on a case of turning under the influence of sulphurous ether. He had delivered a living fœtus from a woman whose previous labour had with difficulty been completed by craniotomy. This was the first instance in which ether inhalation had ever been used during labour, and was destined to form the commencement of a new and important epoch in obstetric practice. This was of special importance with regard to the Boston controversy as to priority. This case was the commencement of a series of valuable articles on "Turning as an Alternative to Craniotomy." This patient was an example of early rising, as with Simpson's sanction she rose, dressed, and walked into the next room on the fourth day. At a subsequent meeting he read a paper on the Inhalation of Ether in the Practice of Midwifery, but the original communication on the all-important subject of Chloroform Anæsthesia was read at the Medico-Chirurgical Society on Nov. 10th, 1847. In the same year he read a paper on the use of Guttapercha for Obstetric Instruments, showing its ready adaptability for pessaries. A series of papers on fibroid tumours contained reasons against the induction of abortion when fibroids complicated pregnancy, and suggested the use of the galvanic current to promote atrophy and calcification. The subject of albuminuria in pregnancy occupied his attention also in 1847; in the paper he showed that when convulsions supervened there was a marked diminution in the quantity of urine passed and the amount of urea it contained; and mentioned the greater frequency of this condition in primiparæ than in multiparæ and the tendency to complete cure. In 1854 he discussed the advisability of inducing labour in cases of severe albuminuria, and proposed the method of induction by passing the sound between the membrane and the uterine wall. In 1851 he published a paper on the Communicability of Puerperal Fever, and laid stress on the disease being acquired in the majority of instances, not by direct infection from one to another, but by the aid of a third party, the medical attendant or nurse. The subject of forceps occupied his attention, and he laid down the principle that it was the delayed use of the forceps, not their ready use, in which their supposed danger lay. As regards ovariotomy, he strongly urged, in 1845, the necessity of its performance, and decried the palliative procedure of tapping. Simpson made public through that society an

immense amount of valuable work, impressing them with the magnitude of his powers and the extraordinary fertility of his brain. His entire efforts seemed to have been concentrated in the attempt to diminish suffering. Wealth and fame had to him no attractions. Interest in his work absorbed him; a freak in the Cowgate would attract him from a houseful of patients redolent with the *élite* of Great Britain. His influence on the medical school was remarkable, and he was ever ready to help and stimulate younger workers and to give praise where it was due. In conclusion, Dr. Haultain advocated the commemoration of the centenary of his birth by erecting a suitable maternity hospital.

The following were the office-bearers elected for the ensuing session:—President: Dr. J. Haig Ferguson. Vice-Presidents: senior, Dr. N. T. Brewis; junior, Dr. J. W. Ballantyne. Treasurer: Dr. G. F. Barbour Simpson. Secretaries: Dr. Angus Macdonald and Dr. B. P. Watson. Librarian; Dr. J. Lamond Lackie. Editor of Transactions: Dr. H. Oliphant Nicholson. Members of Council: Dr. W. Craig, Dr. E. H. Lawrence Oliphant, Professor J. A. C. Kynoch, Dr. Kenmure D. Melville, Dr. F. W. N. Haultain, Sir J. Halliday Croom, Dr. William Fordyce, and Dr. A. M. Malcolmson.

LIVERPOOL MEDICAL INSTITUTION.

Albumin Reaction in Tuberculous Sputum.—Orthopædic Surgery.—A New Cell Proliferant.

A MEETING of this society was held on Nov. 9th, Dr. T. R BRADSHAW, the President, being in the chair.

Dr. NATHAN RAW read a note on the Albumin Reaction in Tuberculous Sputum. He said that Lesieur and Prirey had found this reaction present in 75 per cent. of cases before the appearance of physical signs. Dr. Raw gave his own experience of the value of this test, which he said was, on the whole, favourable.—Dr. W. B. WARRINGTON and others mentioned some difficulties in the way of the application of the test.

Mr. ROBERT JONES described several operations in Orthopædic Surgery—(1) an operation for extreme claw-foot; (2) an operation for ankylosed tubercular shoulder; and (3) removal of bone wedges with interval fracture.—Mr. RUSHTON PARKER thought that the methods mentioned were worthy of praise and support.—With regard to the operation on the shoulder-joint, Mr. JONES said that sinuses were rather rare. If present he would, as a rule, wait until healing had taken place.

Dr. C. J. MACALISTER communicated a paper on a New Cell Proliferant, the investigation of which had originated from the study of the Symphytum or common comfrey. In the old literature of medicine the root of this plant was invariably referred to as being a valuable vulnerary, and although long abandoned by the profession it was still much used by country people as a dressing for sores. Having been much impressed with the importance which was attached to comfrey in the past and with the recorded cases which seemed to benefit from it, he proceeded to investigate it. On being analysed by Dr. Titherley and Mr. Coppin, of the chemical department of the University, it was found to be rich in allantoin which was afterwards prepared synthetically, and on experimenting with solutions of this substance it was found to act as a potent cell proliferant. Dr. Macalister quoted the observations which he had made himself and which others had made for him with ulcers of various types dressed with allantoin solutions with a view to test its efficacy, and there was no doubt that it had accelerated epithelial growth and that it would prove useful in the future for the treatment of ulcerative conditions.—Several members gave evidence as to the value of the drug as applied by Dr. Macalister.—Mr. PARKER thought that some surgeons too seldom thoroughly acquired the principles underlying the accurate management of ulcers.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A clinical meeting of this society was held at the Royal Sussex County Hospital on Nov. 8th.—Dr. E. Hobhouse exhibited: 1. A case of Tumour of the Optic Thalamus in a male aged 19, who had double optic neuritis, with marked tremor of the intention type, and some weakness and ataxy of the right arm. There was no astereognosis or anæsthesia, or other symptoms. He was improving without any treatment. 2. A case of Anterior Poliomyelitis in a young man of the paraplegic type. At the commencement of the attack there was a good deal of pain in the legs, but now sensation was quite normal. He was making a good recovery, being able to walk, although somewhat lame.—Dr. W. Broadbent showed: 1. A woman who several years ago had a Pneumothorax on the right side, with the heart displaced to the left. The air had become absorbed but the lung remained collapsed; consequently the heart had been drawn over to the right until the apex was in the right vertical nipple line. 2. A case of Early Myxœdema in a woman which was improving under thyroid extract. There was still some solid œdema of the face, and her hair was falling out. The skin had been dry and she was very lethargic. 3. A youth aged 20 with Right Hemiplegia and Aphasia of Embolic Origin, which came on suddenly nine months ago. He had aortic regurgitation, with a loud diastolic murmur over the base of the heart; also a well-marked presystolic murmur at the apex with no evidence of mitral stenosis (Flint's murmur). 4. A man aged 65 with Stokes-Adams Disease. His heart-rate was 28, with an auricular rate of 80. He has syncopal attacks at intervals. He has been under treatment for two years and is able to work in his garden.—Dr. A. Winkelreid Williams showed two cases of Diverse Skin Diseases the nerve origin of which is undecided, but which were localised on definite zoster areas. 1. Linear Morphœa in a young woman in which there were two wide streaks, an oblique one on the left parietal region of the scalp and a vertical one on the forehead extending up into the scalp just to the left side of the middle line. Both patches were in the atrophic stage, the disease having lasted 12 years. Both showed a distinct atrophic groove in the underlying bone. The area affected is supplied by the two branches of the frontal nerve, the supra-trochlear and supra-orbital, the defect being probably in the Gasserian ganglion. 2. A Verrucose Nævus in a child aged 7. The condition was first noticed at six months of age. It mapped out exactly the area of the third cervical nerve as depicted in Head and Campbell's monograph on the pathology of herpes zoster. The patient is under treatment with solid CO_2.—Mr. A. H. Buck showed a case of Excision of a Tuberculous Knee-joint in a girl aged 19. The knee was first treated for seven months in a Mackintyre splint, which reduced the swelling and straightened the limb. It was then put into a Thomas's splint for six months, but it still remained painful when any weight was put on it owing to stretching of adhesions. The knee was therefore excised, the patella being saved by division, shaving off the posterior aspect, and uniting by wire at the end of the operation. The result after 12 months' walking was a perfect position, and as good utility as could be expected after excision.—Mr. A. G. Bate (for Mr. T. H. Ionides) exhibited: 1. A case of Paralysis of the Deltoid, Supraspinatus, and Infraspinatus, due to a lesion of the brachial plexus caused by a fall on the shoulder. 2. A patient with Symmetrical Painless Swellings of the Hands. Skiagrams showed that the process involved the bones also with the same symmetry. The terminal phalanges were rarefied, especially in the little finger; the other phalanges showed at their distal ends absorption, which gave to them the appearance of having been drilled with a gimlet. The degree of swelling seemed to correspond in each finger with the severity of the underlying bone condition. There was no history of syphilis and Wassermann's and von Pirquet's tests were negative. There was no sign of any nervous lesion, peripheral, spinal, or cerebral. The general health of the patient was excellent and the disease had developed without any demonstrable cause. It was suggested that the condition was a neuropathy, of a nature allied to that seen occasionally in syringomyelia.—Dr. H. Galt showed the following specimens: 1. Aneurysm of the Transverse and Part of the Descending Arch of the Aorta. There was much firm laminated clot. The bodies of the second, third, and fourth dorsal vertebræ were much eroded, the intervertebral discs being prominent as usual. The sac had ruptured into the œsophagus. 2. Typhoid Ulcers in the Ileum. The Peyer's patches were involved almost exclusively. 3. Two Longitudinal Sections of the Femur in Pernicious Anæmia, and one from a case of Spleno-medullary Leukæmia. 4. The Central Nervous System from a case of melanosis secondary to a diffuse hairy mole of the surface of the body, which was also pigmented. The pigment in the nervous

system was deposited in the pia mostly around the normal nerve tissue, but the temporo-sphenoidal lobe was practically converted into a melanotic mass or true melanotic sarcoma. 5. An Ovarian Cyst from a girl aged 10. 6. Pregnancy in One Division of a Double Uterus. 7. Acute Endocarditis involving the wall of the left auricle. At an earlier date the mitral valve was involved from a streptococcal infection, while the endocarditis of the auricular wall was due to a pneumococcal infection. 8. Advanced Atheroma of the Circle of Willis, one vertebral artery being completely occluded, and also some of the smaller branches. There was extensive paresis. 9. Marked Funnel-shaped Deformity of the Mitral Valve with General Thickening. 10. Patent Foramen Ovale. 11. Sarcoma of the Ovary. 12. Blood Films from a case of Spleno-medullary Leucocythæmia, showing an enormous Leucocytosis. 13. Photographs of a case of a General Yielding of the Lower Abdominal Wall. This followed a laparotomy some years ago, but as far as the skin was concerned the scar had not given.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 9th, Dr. E. Knight, the President, being in the chair.—Mr. G. E. Mould, in opening a discussion on Simple Melancholia, said that simple melancholia—i.e., melancholia without delusions—was essentially the same disease as delusional melancholia. Whether the one would pass into the other was determined by the degree of instability of the nervous system and by the strength of the deleterious influences brought to bear upon it. The division was an artificial one, yet it marked both an important stage in the disease and a starting-point for a different line of treatment, raising the question whether the patient was insane, and if insane whether he was certifiable. The simple melancholic was insane from the medical point of view. Whether he was from the legal point of view depended upon whether he was suicidal. Putting aside the question of identity of melancholia and mania, melancholia was a definite disease presenting definite physical signs and a characteristic mental state, but the physical signs might be absent in the earlier or less-developed simple form. It was indeed the most horrible and cruel affliction that could befall any conscious being. Such a condition was very different from physiological melancholia, better referred to by the English name—melancholy. The simple melancholic, with his intellect practically unimpaired, would constantly cast about for a fresh cause for his misery, attributing it to errors of conduct or of living. An unstable nervous system being the prime cause, they found, as they would expect, an ancestry showing examples of insanity, epilepsy, alcoholism, gout, asthma, and particularly phthisis. Adverse influences came into play at critical periods, puberty, adolescence, before or after childbirth, climacteric, and senility. Uncommon at puberty, when the feelings were undeveloped, it was seen most typically at adolescence and onwards to middle life when the feelings and emotions were most intense. At that period, however, there was a great recuperative power, so that the simple was less likely to pass into the delusional form than later. At the later periods there was not such an active sense of misery. They could soon see by its stationary character that a simple was not going to pass into a delusional attack, and then they knew that recovery was merely a matter of time, if they could guard against the danger of suicide. The majority of simple melancholics were not actively suicidal. They were intelligent. They remembered what they used to feel about life, and could understand when told that they would be capable of feeling the same again. They had considerable will power, enabling them to live in hope without the ordinary inducements of mankind. What they had to do was to gain time. The most important thing was to place the patient under the right man. He must be taught to see life through the eyes of another, until such time as he was capable of seeing it sanely through his own. Differential diagnosis had to be made from neurasthenia, psychasthenia, hysteria, and hypochondriasis, apart from the question whether the simple melancholia was the preliminary stage of delusional melancholia, mania, general paralysis, and dementia præcox. Fatigue was not a symptom of melancholia, as it was of neurasthenia, as evidenced by simple melancholics often undergoing severe exertions to try to rid themselves of their despairing sense of misery, and delusional cases pacing to and fro all day or standing contentedly upright. Psychasthenics were only intermittently anxious and fearful. Hysteria was very characteristic; also its manifestation took place in public. The melancholic would pull himself together in company. Hypochondriasis was more allied to chronic delusional insanity. The question might be complicated by the occurrence of several of the neuroses in the same person. An acute attack of simple melancholia might come on and pass away in a neurasthenic, or a "phobia" or obsession might come on and outlast an attack of simple melancholia.—Dr. Arthur J. Hall referred to the difficulty of diagnosis. Melancholy was a symptom, not a disease. It might be physiological and the absence of grief pathological. It was difficult to distinguish delusions from various types of "phobia," particularly when they were associated with considerations of personal health. In discussing the treatment of melancholics he laid particular stress on the importance of listening carefully and with interest to everything the patient had to say, however trivial and often repeated, and to follow that by a complete and exhaustive physical examination. This served two purposes: first, to be quite sure that there was no organic basis for the condition, and secondly, to be able to satisfy the patient's protean complaints of visceral disease. As regards treatment the main objects were fourfold: (1) to remove the cause; (2) to prevent harm; (3) to relieve symptoms; and (4) to get over time. As regards relieving symptoms, he spoke of several simple methods of dealing with insomnia, and urged their use in order to avoid, as far as possible, the use of drugs.—Dr. A. L. Husband said that it was of the greatest consequence to gain the patient's confidence, and much depended on the individuality of the medical attendant. It was important, if possible, to supply new interests in life. He was of opinion that many of the peculiar "phobias" were attributable to refractive errors.—Mr. A. C. Turner defined melancholia as a saturated solution of grief with decreased objective consciousness and increased subjective consciousness. In delusional melancholia if one delusion was wiped out another would most likely take its place. In making the physical examination they should be especially careful to look out for anything that might give rise to his delusions, such as bad teeth in cases of poisoning delusions. They should not begin by trying to prove to him that his delusions had no foundation.—Dr. Sinclair White showed: (1) A case of supposed Epithelioma of the Tongue in a woman who had long-standing leukoplakia; and (2) a woman with a Tumour of the Breast, which was probably a cystic adenoma, but had many characteristics signs of malignancy.—Dr. Percival J. Hay showed a child with the rare condition of Coloboma of both Upper and Lower Lids of the Right Eye.—Mr. W. S. Kerr showed a man with a large Choanal Polypus which filled up the naso-pharynx and appeared below the soft palate.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 15th, Dr. F. H. Jacob, the President, being in the chair.—Dr. J. Lyn Dimond read a paper on the Treatment of Bacterial Disease by Vaccines. He pointed out that the production of passive immunity by sera was disappointing. Of the two varieties of sera, (1) antitoxic or neutralising, and (2) antibacterial or curative, the antitoxin of diphtheria in (1) and the antistreptococcic serum in (2) had alone fulfilled to any extent the hopes of their investigators. Though vaccines could be administered without control in many cases, the opsonic index or other methods of investigating the immunity reaction was absolutely necessary in order to obtain the best and quickest results. It was probable that one of the quantitative modifications of the Bordet-Gengou reaction would ultimately replace the opsonic index. White's "pus-film" method was an extremely quick and reliable method of controlling inoculations in pyogenic diseases. Arneth's method of counting the number of lobules in the polymorphonuclear leucocytes gave information which helped the control of the inoculations; where there had been a succession of severe negative phases there was a definite movement to the left side of the figures representing the percentages. The subcutaneous route for the administration of vaccines was a necessity. The following examples might be given: (1) The subcutaneous injection of the diphtheria toxin brought about a much greater yield of antitoxin than intramuscular injections; (2) in antityphoid inoculations where there was a

great local reaction the protection was greater than where local reaction was slight and there were marked constitutional symptoms. There was no effect on the index after oral or rectal administration, and only slight after intravenous injections. Rest was a necessary factor in vaccine treatment in order to prevent excessive auto-inoculations. In the treatment of ulcerated malignant disease autogenous vaccines prepared by growth on media manufactured from the patient's own new-growth tissue undoubtedly produced resolution of new growth in addition to healing of ulcers, &c. Chemical sterilisation, at any rate in the case of such organisms as pneumococci, Friedländer's organism, and streptococci, was superior from a therapeutic standpoint to heat sterilisation. Koch's old tuberculin was superior to tuberculin R. and B.E in the treatment of tuberculous adenitis in children. Tuberculin B.E. was a specific for those cases of pulmonary phthisis coming under Turban's Class I. and in which the diagnosis had been verified by the injection of old tuberculin. The speaker illustrated the principles of vaccine-therapy by clinical notes of three consecutive cases of post-partum toxæmia due to streptococcus fæcalis.—Dr. C. H. Cattle, Dr. A. R. Tweedy, Dr. W. T. Rowe, Dr. J. Mackenzie, Dr. H. J. Neilson, Dr. E. H. M. Milligan, Dr. B. Freer (Grantham), and the President joined in the subsequent discussion.

THE NEW LONDON DERMATOLOGICAL SOCIETY.—A meeting of this society was held on Nov. 9th.—Dr. David Walsh read a short summary of a paper upon the Influence of Cardiac Disease upon Cutaneous Disorders.—Dr. Tom Robinson showed: 1. A man previously exhibited at the meetings with an Infiltrated Lesion upon the back of the Right Hand in which X rays had not caused much improvement. 2. A man with a lumpy Sycosis, clinically resembling Tinea Barbæ, but neither spores nor mycelium had been found on microscopic examination.—Dr. W. Knowsley Sibley showed: 1. Two boys, aged 10 and 7 respectively, who had had numerous patches of Multiple Lupus scattered over the limbs and body, following upon measles. The treatment had consisted in the application of solid carbon dioxide followed by the application of X rays. Several of the lesions had healed beautifully. 2. A young man, aged 23, with recent Lupus Erythematosus of the Face, who presented the typical "chilblain circulation."—Dr. G. Norman Meachen showed: 1. A case of Lupus Erythematosus in a girl of 7 of four months' duration. The rarity of the disease at this age was commented upon. 2. A case of Tertiary Syphilide of the Face in a woman of 36, clinically resembling a seborrhœide. The patient also gave a strong family history of tubercle. 3. A young man with Multiple Lupus following upon measles and varicella. Numerous scars, some of which were due to varicella only, were present upon the limbs and face.

PADDINGTON GREEN CHILDREN'S HOSPITAL.—Her Royal Highness the Princess Louise, Duchess of Argyll, visited the Paddington Green Children's Hospital on Nov. 16th, in order to declare open the new out-patient department. Her Royal Highness was received by Mr. Douglas Owen, chairman of the committee; Mr. George Hanbury, treasurer; and the members of the hospital staff. Mr. Owen gave a brief history of the hospital and of the circumstances which had led up to the present important extension. Thirty years ago, he said, it was decided to replace the North-West London Free Dispensary, near Lissongrove, by a cottage hospital for children, and mainly owing to the personal efforts of Mr. Hanbury two newly erected houses on the present site were purchased for the purpose. This hospital was opened in 1883 with 23 beds. In 1892 the hospital was demolished and a new building erected. The out-patient accommodation soon became quite inadequate, and the new buildings had been provided at a cost of about £11,000. Unfortunately, there was still a debt of £2000 on the buildings. Sir Frederick Milner and Sir Henry Seton-Karr having moved and seconded a vote of thanks to the Princess for her kindness in attending, the Duke of Argyll replied and emphasised the importance of societies for the education of mothers in the healthy up-bringing of their children. A large number of purses were then presented by children to Her Royal Highness, who was afterwards conducted over the new building. The Princess then inspected the display of articles contributed by the Ladies' Work Association, and finally visited the wards.

Reviews and Notices of Books.

On Diseases of the Lungs and Pleura, including Tuberculosis and Mediastinal Growths. By Sir R. DOUGLAS POWELL, Bart., K.C.V.O., M.D. Lond., F.R.C.P. Lond., Hon. D.Sc. Oxon., M.D. Dub., F.R.C.P. Irel., LL.D. Aberd. and Birm., Physician in Ordinary to His Majesty the King; and P. HORTON-SMITH HARTLEY, M.V.O., M.A., M.D. Cantab., F.R.C.P. Lond. Fifth edition. With 29 plates (6 in colours). London: H. K. Lewis. 1911. Pp. 712. Price 21*s.* net.

THE new edition of this standard work on Diseases of the Lungs will be cordially welcomed by the medical profession, for it embraces the matured doctrines of a great authority who has not blindly accepted new views of the treatment and etiology of the affections in question, and in addition the results of the experience of a younger physician still on the acting staff of the Brompton Hospital—that storehouse of facts concerning thoracic ailments. Eighteen years have elapsed since the last edition of the work was issued. During this period the science of medicine in relation to diseases of the lungs has seen many changes. The authors have not hastily published their facts, for they tell us in the preface that well-nigh ten years have been spent in the production of the present edition. Every sentence of the former edition has been revised, many additions have been made, and much has been altered or eliminated in the light of the interval that has elapsed since the previous issue.

The account given of the essential points in the anatomy and functions of the lungs remains but little altered from the previous edition—no necessity whatever for any real modifications has arisen—but an effective X ray photograph has been inserted showing the normal distribution and general arrangement of the bronchial tree after Dr. W. Brünings. In the chapters on the Physical Examination of the Chest the excellent table setting forth the terminology and common significance of the facts elicited by palpation and auscultation is retained. It is a matter of regret that the terms there employed, which were carefully selected by Sir R. Douglas Powell and by the late Dr. Mahomed, acting as English members of a committee nominated at the International Congress held in London in 1881, have not been more generally adopted. Much confusion still exists in this respect, as various authorities employ different terms to indicate the same physical signs, and uniformity is much to be desired. We recommend for general adoption the nomenclature here chosen.

The examination of the sputum is fully dealt with; this is illustrated by two beautiful plates showing Curschmann's spirals. These plates were in the previous edition of this work. The deformities and diseases of the chest wall then claim attention. The morbid conditions of the pleura are set forth under the various sections embracing the different forms of pleurisy, the subjects of hydro- and pyo-pneumothorax, hæmothorax, hæmopneumothorax, and chylothorax. The authors point out that the majority of the primary cases of acute sero-fibrinous pleurisy arising *de novo* do not owe their existence to exposure to cold or draught, as was formerly thought, but are really tuberculous in nature. The account of the clinical symptoms is excellent, whilst the whole subject of paracentesis thoracis is treated in a masterly fashion.

In discussing the diseases of the bronchi the section is illustrated by a speaking plate showing the casts expectorated in plastic bronchitis. This plate was also in the last edition. In their remarks on the pathology of asthma the authors express the view, confirmed by the researches of C. J. B. Williams and of Brodie and Dixon,

that the theory of bronchial spasm would be adequate to explain the asthmatic attack. A full description of the various remedies found useful for correcting the spasm, and of the methods of using them, is given. A wise warning is inserted to beware of prescribing too freely the hypodermic injection of morphia. In the chapter on emphysema the authors give an interesting section on aerotherapeutics: this method of treatment is certainly of benefit in many, although not in all, cases. In discussing the causation of pneumonia it is stated that cold is by far the commonest cause of the disease. This opinion, which is certainly the one held in England, does not seem to obtain universally. Dr. Sanders, in a paper published some years ago in the *International Journal of Medical Science*, showed by statistics that "pneumonia, other things being equal, increases uniformly in frequency the nearer we approach the equator. That is to say—and the fact is a surprising one and one distinctly opposed to its presumed dependence upon cold—the disease is more frequently met with, and is more common, in warm than in cold climates, showing a gradually increasing ratio from the Pole to the Equator." This statement of Dr. Sanders would appear to be borne out by the experience of Indian physicians. An epidemic form of pneumonia is met with pretty frequently in the Punjab and on the North-West Frontier. With regard to the treatment of this disease the authors evidently do not believe in that valuable old remedy antimony.

Without attempting to indicate the alterations and additions which have been made in this edition, we naturally turn to those subjects which have been prominently before the profession in order to ascertain the conclusions arrived at by the authors in their extensive experience. The subject of pulmonary tuberculosis occupies a large portion of the volume, and in political and general circles, as also amongst the profession, the treatment of this affection is receiving an unusual amount of attention. It has been brought home to us all that in the prevention of phthisis we have a possible social reform which will bring benefits that it is quite impossible to estimate. The sanatorium treatment is described at length, and especial attention is drawn to the favourable effect of exercise and work in selected cases. This method has been elaborated at the Brompton Hospital Sanatorium at Frimley under Dr. M. S. Paterson, whose words are quoted; and the authors consider that the results of treatment already published have been gratifying. They also view with favour the contention that has been advanced that the good effects are due in great part to autoinoculation of tuberculin and subsequent immunisation. The conclusions arrived at as to the employment of tuberculin are also of particular interest. We would here draw attention to the fact that after due deliberation the authors decided to follow the more modern German system and to prescribe the remedy by measure only in cubic centimetres and fractions of the same. This method has its advantages if larger doses are employed, but with the more minute doses the number of cyphers which are required are rather bewildering; for instance, the small initial dose of "T.R." which is frequently employed is represented by 0 000,000,001 cubic centimetre. A more convenient method would seem to be to express the amount in fractions of a milligramme; we venture to question whether any benefit to dispensing counterbalances the unwieldy notification. The conclusions as to the results of treatment by tuberculin are expressed clearly and fairly. The authors maintain that the use of tuberculin in one form or another is a rational one, and leads to an increase in the body of opsonins and agglutinins, and presumably of other protective substances; in their own words, they "have no hesitation in recommending a course of tuberculin, provided that the patient possesses sufficient vitality to yield the requisite response demanded by a proper use of the remedy."

The vaccine treatment of pneumonia is discussed, and it is admitted that the results obtained by some observers are on the whole encouraging. The authors have used vaccines in some cases of acute pneumonia, but they are unable to arrive at any determined conviction in regard to their general utility in this disease.

There is an admirable summary of the various climatic resorts to which consumptives may have access, and in the concluding chapter will be found a learned account of intrathoracic tumours.

We congratulate the authors on their work. While space forbids us to comment on all the very interesting contents, we can safely say that no affection of the lungs has escaped the notice of the writers. One of the features in this new edition is the number of excellent illustrations of sections of the lungs, which are beautifully executed.

Manual of Physiology for Students and Practitioners. By H. WILLOUGHBY LYLE, M.D., B.S. Lond., F.R.C.S. Eng. With 1 plate and 135 figures in the text. London: Henry Frowde and Hodder and Stoughton. 1911. Pp. 747. Price 15*s.* net.

IN this manual histology is referred to only in those cases where it directly bears on physiology, and embryology is not included, while diagrams of instruments and details of experiments have, as far as possible, been purposely omitted. The book is none the less a large one, over 700 pages, though by the use of excellent type and well-selected paper the volume has been rendered far from bulky. The author invites friendly criticism, and perhaps this invitation can be best acceded to by taking the list of subjects seriatim—15 sections in all. They are on general and chemical physiology, diet and digestion, cardio-vascular system and allied organs, respiration and allied functions, metabolism, animal heat and the skin, excretion, nervous system, nerve and muscle, the sense organs, and reproduction.

The section on chemical physiology (pp. 13–72) is concise, and due prominence is given to the newer views of the constitution of proteins and the importance of lipoids. "Foundation stones" is hardly, however, the exact translation of the "Bau Steine" of the Germans as applied to the amino-acids. The important subject of diet is considered in 14 pages, while to digestion in the broad sense about 80 pages are given. All this is good. The work of Hertz has been largely drawn upon. We do not think the student could possibly understand Pawlow's gastric pouch from the description given on p. 100, and we are at a loss to know what is meant by "broken cardiac compensation" on p. 125. A new form of energy, the biotic energy of Moore, is invoked as being mainly the cause of absorption of the products of digestion by the villi. Surely the experiments on deglutition referred to on p. 148 were made by Kronecker and Meltzer, and not Maltzer.

About 60 pages are devoted to the cardio-vascular system. The heart is said to "consist of four chambers—two auricles placed above a fibrous plate and two ventricles below it." The author is not at his best in describing anatomical details. The right ventricle is said to have "a strand of muscle fibres stretching across its cavity from the wall to the septum, the moderator band." No free moderator band exists in man, though one occurs in the heart of the sheep. On p. 183 there is another misprint, Starling instead of Stirling, while the famous experiment on the depressor nerve is attributed to Ludwig and Lyon, instead of Cyon.

Blood is dealt with in about 40 pages, but nothing is said about its viscosity, and some of the statements require revision. In describing the functions of the colourless blood corpuscles, the author says that "they are the carriers of the blood-stream and of the lymph

stream" (p. 248), but surely there are other carriers in the blood stream. Tannic acid does not usually cause the oxyhæmoglobin in frogs' corpuscles to collect into a small globule and become attached to the nucleus; on the contrary, as described by Roberts long ago, "pullulation," or the formation of little globules, appears on the surface of the corpuscle. Blood is said to be opaque "because it contains solid elements," but the mere presence of solid elements is not the cause of the opacity of the blood. The occurrence in this section of the word "suitable" as a misprint for "stable" is a little indication that close revision has not been carried on.

The important subject of metabolism occupies about 60 pages. The author seems at his best in dealing with the chemical part of physiology, and this chapter is both instructive and concise. About 40 pages suffice for excretion, including the kidneys and the urine. To the nervous system about 120 pages are allotted, and here we find at one place "artefacts" and at another "artifacts." The discovery of the T-shaped division of the axis-cylinder of a unipolar nerve cell is attributed to Remak. Surely it was not Remak, but Ranvier, who discovered it. Twenty pages are devoted to muscle, and to the senses about 80 pages. Here some of the diagrams are rather crude, but the text gives so good a summary of the leading facts and theories that they probably serve their purpose.

There are practically no dates given to indicate what is recent and what is not. There is nothing to guide the student as to when the beginnings of real discoveries in cerebral localisation were made. Quantities are sometimes given in "grs.," "drms.," and sometimes in the metric form; measurements sometimes in inches, sometimes in centimetres. And lastly there are too many misprints and slips. We find, for example, "vitale" for "vital," "twist" for "twitch," "worked" for "washed," "heart" for "heat," and "motor cord organs" for "motor end organs," while we can assure the author that his interesting book has been read with no desire to pick small faults.

The author conveys a large amount of physiological information in this manual, which the average student of medicine will find a useful, well-proportioned, and handy compilation. Because the book is in essentials so good and thoughtful we have pointed out small blemishes which can be removed in editing the work for further issues.

Public Hygiene. By T. S. BLAIR, M.D., assisted by Numerous Contributors. Two Volumes. London: Rebman, Limited. 1911. Pp. 644 and 158 illustrations. Price 42*s.* net.

Dr. Blair, of Harrisburg, Pennsylvania, the author of several works on medical treatment, has been led to turn his attention to public hygiene from his conviction that this subject has "developed too much as a specialty and needs the tempering conclusions of the whole body of the medical profession"; and in these volumes he has aimed at informing the rank and file of the profession on the public work which is done in America in the interests of health, whether by the Legislature and officials, or by individual firms and corporations for the benefit of their employees or customers.

So that his writings should relate to "a basis of real accomplishment rather than that of a propaganda," the author has made many trips of inspection, annexed information from all sources, obtained illustrations of every kind (including photographs of medical missionaries and model ironworks), and on many of his subjects has secured contributions by experts and copious extracts from official documents. There are chapters on hotels, maternities, places of amusement and dissipation, State departments and boards of health, hygiene of camps, internal sanitary installations of houses, public works, and many other matters, on all of which Dr. Blair imparts much useful information, together with not a little gossip and occasional criticism of the shams (the "flub-dub," if we may use his word), which have come under his notice. While giving high praise to the results of local administration in the different States, he is keenly alive to the dangers of ignorant interference on the part of unqualified inspectors and officials appointed on political grounds, and is by no means carried away by the sentimentalists. Thus, on the health of foreign coal-miners, "it is very easy to criticize the brutal mine boss: very much easier than it is to boss a gang of dagoes. Also, be it remarked, the average dago has no idea the boss is being brutal. As to sanitation, the bed bugs are so thick in the shanties that the mere microbes have no chance. The foreign section in a mining town will begin to be sanitary when the law requires that it be burned down twice a year."

The book is well indexed, and deserves to be remembered as a repository of notes on many subjects on which information is not always readily obtainable. The heating of American houses and offices, rules for inspection of illuminating oils, and the sanitation of penal institutions are instances in point. The section on Public Carriage and Sanitation is particularly full, and includes regulations in force for cleansing and disinfecting railway carriages, notes on ventilation and warming of cars, and like matters. We are afraid that the "proper house drainage" illustrated on p. 390 would be rejected in any British municipality. Dr. Blair, by the way, boldly prophesies that "in England the time will soon be that the doctor will wear a State uniform and live upon a State salary."

Grundriss der Zoologie und vergleichenden Anatomie für Studierende der Medizin und Veterinärmedizin. By ALEXANDER BRANDT. Berlin: Hirschwald. 1911. Pp. 647. Figs. 685 in text. Price 14 marks.

THE output of elementary works on zoology seems to be fully as great in Germany as in England, and rather contradicts the prevailing impression that the study of this science has suffered some eclipse of late years. For a book like the present—and there are many of the same character appearing at intervals—is emphatically for the student and not for the general reader with no examination in immediate view. And the publication of such text-books implies at least the existence of a class for which they are intended.

The present volume is reminiscent of the very well-known text-book, Railliet's "Zoologie Médicale et Agricole," which has a scope very similar to that of the volume under review. The French professor, however, has catered more fully for his veterinary readers than has Dr. Brandt. The parasitic worms naturally form a distinct feature of Dr. Brandt's volume and thus mark it out from text-books which aim only at a general sketch of the animal kingdom. It is much more important for the student of medicine, whether he proposes to deal with human beings or with domestic animals, to have a full knowledge of tapeworms and nematoids than of the systematic position of balanoglossus or of the main sub-divisions of the echinodermata.

Dr. Brandt, however, gives a good account of the worms in question, though it is not very full as regards the domestic animals. Nearly all the tapeworms belonging to the division of tetracotylea (and to this division nearly all the worms infesting the higher vertebrated animals belong) are relegated to the genus tænia, which is thus used in an antiquated and now effete sense, the genera monieza and drepanidotænia being excepted. Furthermore, while the human tapeworms are treated fairly exhaustively, the section dealing with worms that occur in fowls is too short to be of any use. The author, in fact, only mentions drepanidotænia infundibuliformis (which is properly choanotænia infundibulum) and ligula as occurring in birds. Many species in

reality frequent the intestinal tract of Gallus. The necessity for compression and consequent omission has led the author into dealing in a very "stepmotherly" fashion (as his countrymen say) with other groups of the animal kingdom. But the protozoa are treated with commendable fulness—comparatively speaking. Dr. Brandt has, in fact, a good deal to say concerning trypanosomes and spirochætæ, which are of such enormous importance in medicine.

The pages in which the characters of the vertebrata are set forth are naturally many, in view of the large size of that group and the many types which must be touched upon, since they are familiar to everyone. An illustration of the posterior lymph hearts of the frog is interesting. The actual species of frog which has been selected is not identified, but each lymph heart consists, according to the illustration, of two more or less completely separated "hearts." It is usually and quite positively stated that each of these organs of propulsion of the lymphatic system in the common frog is a single organ with but one cavity; this is the view of most students' text-books. But several continental authorities, including no less a person than Professor Ranvier, have alleged the contrary, while there is absolutely no doubt about the fact that the great frog from the Solomon Islands, known as Rana guppyi, has each of its lymph hearts divided by an internal septum into two spaces. Thus Dr. Brandt has found himself plunged into an anatomical squabble, holding, however, a definite opinion on its merits.

The author, indeed, is not contentious; he deals with such controversial subjects as occur in his survey without acrimony. If views are very divergent he merely indicates that there is divergence. Especially is this the case during the pages at the commencement of the book, in which he sets forth the results of opinion as to some of the more general principles of zoology, such as the definition of species, the origin of variation, geographical distribution, and so forth. This section, which appears to us very well placed, precedes the middle part of the volume; this is by far the longer and contains an enumeration of the characters of the subdivisions of the animal world. The book concludes with a comparative anatomical section, which is mainly vertebrate in its scope. Few errors or obvious misprints have been noticed. One instance, however, must be mentioned as it might deceive. In giving the characters of the oligochætous worms Dr. Brandt writes of the large Australian earthworm originally described by the late Professor McCoy of Melbourne, and later by his successor in the chair, Professor Baldwin Spencer, as "macroscelides." He should of course have written megascolides, for macroscelides is an insectivorous mammal.

The Town Child. By R. A. BRAY. Revised edition. London: T. Fisher Unwin. 1911. Pp. 255. Price 3*s.* 6*d.*

IT is little surprising that a second edition of this book has been called for. It deals with one of the chief problems of the age, perhaps the chief—the education, physical, intellectual, and moral, of the child, the State's citizen in embryo. Few people have had better opportunities of watching the "growing child" than Mr. Bray, for he has lived for many years among school children and in schools; he is well equipped, therefore, with the necessary experience. But even more important than this experience for the making of a good book is his lucidity of style. Mr. Bray thinks clearly and writes clearly. Although there is a great deal in "The Town Child" that by no feat of legerdemain can be directed into the service of medicine, none the less there are many chapters that may be read with undoubted advantage by the school medical officer, and indeed by others of our profession who are concerned with the supervision of the health of children.

As the author fully explains, the environment of the town child is human and psychological, differing thus fundamentally from that of the country child, whose environment is that of trees and flowers and vegetables and animals. And since our health, like our diseases, must depend much on environment, it is a matter of the greatest importance for the medical man to study the true relations in the matter.

In Part I. Mr. Bray deals with the problem of the town, the environment of man, and man and the environment. In Part II. he describes the needs of education, social and religious, of the school child, but the medical reader will probably direct his chief attention to those sections which are concerned with the physical well-being of the child. There is no part of the book that is more worthy of attention than that concerned with the establishment of habits; in a physiological sense medical men realise the importance and significance of habits, but as regards their wider significance they would do well to study the canons laid down by the author for their better establishment. "First," he says, "we want habits, because habits alone render tolerable the drudgery and the routine of life and secure stability of character. Looking at the life of the town child and taking into account the influence of the environment, we need chiefly habits of regularity, habits of attention, habits of order, habits of self-control, and habits of cleanliness, using the last term in its widest significance." Mr. Bray has made an honest attempt to indicate how the attainment of these much needed elements in character can be secured through the instrumentality of our educational machinery.

"The Town Child" is altogether an inspiriting work.

Theorie und Praxis der Inneren Medizin. Ein Lehrbuch für Studierende und Aerzte. Von Dr. ERICH KINDBORG in Bonn. Erster Band. *Die Krankheiten der Zirkulations- und Respirationsorgane.* Mit 47 abbildungen. Berlin: S. Karger. 1911. Pp. 404. Price, bound, 7 marks.

Dr. Kindborg gives as his apologia for adding another to the numerous text-books of medicine the fact that he has found that the student often finds difficulty in grasping some of the problems of medicine because he has not available the necessary information afforded by the ancillary medical sciences. He has therefore given in his descriptions of the diseases of which he treats such anatomical, physiological, pharmacological, and other information as may be necessary to explain the matters he is dealing with. These are generally given at the commencement of each section, and are printed in smaller type. Without being in any sense exhaustive they are of sufficient length to be of real value.

The subjects dealt with in this, the first, volume are diseases of the circulatory and respiratory systems. The classification followed by Dr. Kindborg is on conventional lines, but the descriptions he gives of the individual morbid conditions are by no means stereotyped. He writes clearly and well, and his subject-matter is both interesting and practical. We may mention his account of pulmonary tuberculosis as one of the best in the book. After a full description of the tubercle bacillus and its properties, the pathological and clinical features of the disease as it affects the lungs are given. The question of diagnosis by means of the various modifications of the tuberculin test is then discussed and the value of each indicated. In connexion with treatment, a critical and cautious review of the use of tuberculin is given, and due care is urged in regard to dosage and frequency of administration. In general, the sections devoted to treatment are the most exhaustive. Full directions are supplied in regard to the management of the patient, prescriptions are given, and, conforming to the fundamental

principle he had in view, Dr. Kindborg in recommending any drug describes its origin, chemical constitution, and general properties. Authorities are often quoted both in the text and in footnotes.

If the other volumes come up to the standard of the present one, Dr. Kindborg will have produced a valuable and interesting addition to the text-books on medicine.

Lateral Curvature of the Spine and Flat-foot and their Treatment by Exercises. By J. S. KELLETT SMITH, F.R.C.S. Eng.; late Demonstrator of Anatomy at University College, Liverpool. Bristol: John Wright and Sons, Limited; London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1911. Pp. 137. Price 5*s.* 6*d.* net.

IN the preface the author lays down very definitely the scope of his book: "Its chief object is to indicate in a clear and concise manner the steps necessary for the treatment of those cases of spinal curvature which are most likely to occur in general practice," leaving to more elaborate works on orthopædics the description of the high grade cases of scoliosis and the method of making and fitting mechanical supports. We may say at once that he has carried out this idea admirably.

The photographic illustrations are good and demonstrate very well the different exercises that are explained in the text. Mr. Kellett Smith gives in the first chapter an interesting extract from a work by Pierre Dionis, written in 1707, and he draws attention to the fact that until recently with little alteration and few additions the text would very well have done for a description of the treatment employed for lateral curvature at the present time. The last decade has seen the growth of systems of exercises without number, but recent teaching is tending in the right direction. It now condemns the old form of physical training, in which a pupil was introduced into a gymnasium and was taught dumb-bell, club, and bar-bell exercises, and was then left to roam at will amongst a profusion of apparatus, instead of each case of scoliosis being treated on its own merits and exercises being prescribed suited to the strength of the patient and to the correction of the deformity. A useful chapter deals with the general treatment which is likely to be required by subjects of spinal curvature.

This is eminently a book suited for the general practitioner wishful to treat the slighter forms of scoliosis or pes planus.

Les Syncinésies. Leurs Rapports avec les Fonctions d'Inhibition Motrice. By Dr. G. STROEHLIN, Ancien Interne des Hôpitaux de Paris. Paris: G. Steinheil. 1911. Pp. 148.

THE tendency which is characteristic of infancy to make movements bilateral and symmetrical gradually disappears under the influence of education and of the development of the motor paths, but under certain pathological conditions—e.g., infantile hemiplegia, adult hemiplegia—this primitive motor bilaterality reappears and reveals itself by associated movements. These, as a rule, cannot be repressed or diminished by voluntary effort; they are seen only on voluntary muscular activity, and they are more pronounced on one side of the body than the other. Dr. Stroehlin supplies numerous personal observations of associated movements, and suggests an eclectic hypothesis, based on the well-known views of Hitzig and of Westphal, to account for the phenomena. The appearance of these synkineses depends on lesions of the pyramidal tract, and the author utilises a term coined by Dupré—"débilité motrice d'inhibition"—to express the symptoms by which this defect of the pyramidal system reveals itself. The syndrome consists of increase in the tendon reflexes, alteration of the plantar reflex, awkwardness of voluntary movement, paratonus, and synkinesis or associated movement. A bibliography is appended to the thesis.

LIBRARY TABLE.

On Variations in Chromosomes. By CHARLES EDWARD WALKER. A Reprint from the *Archiv für Zellforschung*, Band 6, Heft 4. Leipsic: W. Engelmann. 1911.—This paper records a series of interesting observations on the variations in shape and size of "chromosomes of an ordinary kind that are found in certain cells of the organism always, and not with a special form which is found only in the cells of particular animals and of individuals of one sex and not in those of individuals of the opposite sex." Previous observations bearing on this point have been mainly or wholly confined to cells in the last-named category. This paper must be read in close connexion with the author's book on "Hereditary Characters and their Modes of Transmission," which was noticed in THE LANCET of Dec. 3rd, 1910. In this work is suggested the theory that the chromosomes are the bearers of *individual* variations, while the cell as a whole is the bearer of *racial* traits. The author argues that if the establishment of the fact that chromosomes vary constantly in form and size be accomplished, then one step further towards the origin of variations is attained. It seems clear that more observations are wanted before this constant variation in form and size can be established. Should it be established, it would lend some additional colour to the author's hypothesis above referred to, but could not be held to prove it. His present position appears to be that he considers chromosomes *because* they vary to be the bearers of individual characters as opposed to racial; that he claims "Mendelian" characters as individual; and that he assumes that the *inheritance* of these, not the *reproduction* merely, is alternative. He therefore appears to think that there is no *patency and latency*. In the summing-up of this paper the author's belief is reiterated that racial characters, that is, characters which are found in *all* the individuals forming a race of animals or plants, cannot be borne by individual chromosomes, because the chromosomes are distributed in an alternative manner to the gametes before fertilisation. He further emphasises the view that "constant and continual variations among chromosomes would account for the constant and continual variations that appear in animals and plants, without necessary recourse to the mutation theory and the assumption that variations occur only in epidemics at intervals, species only arising during these epidemics." This author's careful work as displayed in this paper will doubtless stimulate others to make further observations on the same lines.

Aus Theorie und Praxis der Chemotherapie. Von PAUL EHRLICH. Leipzig: Dr. Werner Klinkhardt. 1911. Pp. 28. Price 1.20 marks.—This is the address given to the Society for Microbiology at Dresden in May, 1911. It deals with Ehrlich's well-known theories regarding chemo-therapeutics, which the author has done so much to elucidate. It discusses the *rationale* of treatment of such diseases as trypanosomiasis, malaria, recurrent fever, and the use by injection of salvarsan, and how the untoward accidents that sometimes accompany its use can be avoided. The author is persuaded that the "intensive" treatment of syphilis in its early stage, according to the methods recommended by himself, adds enormously to permanent recovery. The address is dedicated in a graceful peroration to Professor Waldeyer, of Berlin, who greatly encouraged Ehrlich when the latter was a student under Waldeyer in Strasburg, nearly 40 years ago. It will be interesting to clinicians as well as to biologists.

New Reduction Methods in Volumetric Analysis. By EDMUND KNECHT, Ph.D., M.Sc. Tech., F.I.C., and EVA HIBBERT. London: Longmans, Green, and Co. 1910. Pp. 108. Price 3*s.* net.—The authors deserve a word of thanks for pointing out the practical advantages of using

titanium salts as reducing agents in analysis. Their application is evidently of value, and quite a surprising number of accurate determinations can be made by employing titanous chloride. The salt can be used, for example, as a quantitative reducing agent for metals and their compounds—e.g., iron, copper, tin, chromium; for non-metallic elements and their compounds—e.g., hydrogen peroxide, chlorates, nitrates, oxygen in water; and for organic compounds—e.g., nitro compounds, azo compounds, certain reducible dye stuffs giving colourless compounds, and sugars. The details of analytical work are set forth with clearness, and it is quite obvious that titanous chloride is a valuable material in the analytical laboratory.

JOURNALS AND MAGAZINES.

The Child.—The November issue contains an abstract of the paper on the Hygiene of School Life in Ireland, read before the Royal Sanitary Congress at Belfast, by Professor J. A. Lindsay. Emilia V. Kanthack de Voss discusses in an interesting manner child welfare in Germany. She refers to the modern crowding into towns (which she attributes mainly to "the increasing desire for entertainment and social excitement"), as leaving its mark on the physique and on the spirit of the working-classes. The training of children, home and school life, and training schools are dealt with, and stress is laid on the importance of home life and mother craft in the prevention of physical deterioration. Dr. R. J. Ewart discusses the "Aristocracy of Birth." He dwells on the modern subjection of the primitive attitude of mind—the prevalence of the social "don't" over the individual "do." Even the vital statistics, he says, tell us pessimistically how many per 1000 die, instead of more optimistically informing us how many per 1000 have survived. He uses the death statistics as a figure to subtract from the number living, so as to inquire into the conditions under which the best are born. He discusses the problems of birth under the following heads: (1) age of mother, (2) sequence of birth, (3) interval of birth, (4) season of year at which birth occurs, (5) sex of birth, (6) vague conditions pertaining to general health, included under the term environment, (7) accidental conditions, such as twins or other numerical abnormality, and (8) conditions of sentiment, as judged by illegitimacy. Winifred Brooks Mylechreest writes judiciously of story-telling, the art beloved of children, so necessary to their proper bringing up, yet so neglected. Dr. W. D. Carruthers discusses the school desk, and condemns the long desk with a considerable horizontal interval between the desk and the seat. He describes a dual desk, the seat of which is moveable, and is so divided that each child can move in and out independently of the other, or one may stand while the other sits. Mr. E. D. Telford discusses residential schools for crippled children, on the basis of that instituted in 1905 by the Manchester Education Committee. It has been in existence for six years, and 115 cases have been discharged, with the following results: cured 57, improved 17, discharged unrelieved 33, discharged on time limit 8. The editor of the *Boys' Own Paper* relates its history. Miss Lillias Hamilton, warden of the Studley Agricultural and Horticultural College for Women, gives an illustrated description of that institution. Mr. H. J. Eason furnishes an account of the Manchester Children's Hospital, and Dr. F. E. Batten a summary of what is known of acute poliomyelitis. Various societies are described by their secretaries, and Cheltenham and its educational facilities by Mr. Edward F. Burrow.

The North of England Clinical Journal. The Organ of the Newcastle-upon-Tyne Clinical Society. Edited for the Editorial Committee by Mr. GEORGE FOGGIN, 24, Eldon-square, Newcastle-upon-Tyne. Vol. I., No. 2. September, 1911. Price 1*s.*—The second number of this new journal contains a paper by Dr. J. S. Risien Russell on Important Problems in the Diagnosis of Diseases of the Nervous System. It consists of a practical discourse for men in general practice on everyday problems with which all are liable to be confronted. Dr. R. E. Sedgwick contributes a paper on that bold buccaneer, Dr. Thomas Dover, which adds some features of interest that we do not recall having seen in other articles on the same subject. The late Mr. T. G. Ouston discusses the uses of radium in diseases of the nose and throat. The article is followed by an obituary notice of its author, who died on August 4th. Dr. Harold Kerr gives some public health notes, and Mr. John Clay discusses approvingly the use of indigo carmine in cystoscopy. Dr. T. M. Allison has a note on the Infectivity of Actinomycosis. Clinical reports, reviews, and notices conclude the number.

Man.—The November number of this journal contains a copiously illustrated article by Dr. C. G. Seligmann and Miss Margaret Murray on a hitherto unexplained standard pictorially represented in Upper Egypt. They argue that the object, or emblem, which surmounts the standard is an idealised figure of the placenta concerned in the antenatal life of the king before whom this particular standard was eventually carried.

Reports and Analytical Records
FROM
THE LANCET LABORATORY.

CHOLOGESTIN.

(THOMAS CHRISTY AND CO., 4, 10, & 12, OLD SWAN-LANE, UPPER THAMES-STREET, LONDON, E.C.)

CHOLOGESTIN is described as "a peculiarly eligible method of administering the natural bile acid salt and pancreatin in palatable liquid form, in conditions attended with intestinal putrefaction, auto-toxæmia, and indicanuria." We have confirmed the presence of the active constituents—viz., glycocholic acid and pancreatin. In alkaline solution the preparation showed a marked digestive action upon beef fibre, while a very definite reaction was obtained with Pettenkofer's reagent for biliary acids (glucose dissolved in strong sulphuric acid). Sodium salicylate was also easily detected. Chologestin occurs in the form of a palatable alcoholic fluid (15 per cent.), or in tablets, three of which contain the active medicinal ingredients of one tablespoonful of chologestin. The claims of chologestin merit attention.

"HEALTH AND STRENGTH" COCOA.

(SANDOW, LIMITED, 5 TO 21, NEW KENT-ROAD, ELEPHANT AND CASTLE, S.E.)

Sandow, Limited, as far as the public is concerned, means Mr. Eugen Sandow, and this gentleman has for some time past been engaged in an undertaking which has not commended itself to the medical profession for perfectly obvious reasons. We have been asked by Mr. Sandow to examine and to report upon this cocoa, and in the public interest we do not feel justified in refusing the invitation. We should certainly decline to give publicity to any undertaking in which, as it seemed to us, Mr. Sandow was posing as the possessor of medical knowledge, or in which he seemed to be making an illegitimate use of qualified medical assistance. But because Mr. Sandow's methods in connexion with the cultivation of "physical health" have been so rightly reprobated by all medical men—an attitude that has been endorsed by the General Medical Council—it would not be right to refuse to analyse a foodstuff connected with his name which has been offered to the public. If THE LANCET is to

keep consistently to its attempt to act as an interpreter of the merits and demerits of the public food-supply, we must not allow disinclination of any sort to deter us from making any analysis that the public good demands. Mr. Sandow has been making some very large claims on behalf of this particular cocoa in the public press: it will be seen from the analysis which follows how far they can be substantiated.

The cocoa on analysis gave the following results: Moisture, 5·0 per cent.; mineral matter, 8·10 per cent.; proteins, 25·84 per cent. (equal to nitrogen 4·10 per cent.); fat, 14·76 per cent.; theobromine, 1·34 per cent.; alkalinity of the ash calculated as potash (K_2O), 2 82 per cent. In THE LANCET of Jan. 7th, 1905, a contribution from our laboratory was published on cocoa, which contained the results of analysis made of the various cocoas upon the market. The following ranges in composition were shown: Moisture, 3·0 per cent. to 8·0 per cent.; nitrogenous matter (N × 6·3), 19 0 per cent. to 20·0 per cent.; fat, 26·0 per cent. to 31 0 per cent.; mineral matter, 3·90 per cent. to 8·80 per cent.; theobromine, 1·7 per cent. to 2·0 per cent. By comparing these figures with those obtained with "Health and Strength" cocoa the basis of its claims compared with other cocoas will be understood. It contains, for example, a good deal less fat and an increased proportion of proteins calculated upon the total nitrogen found. It will be also noted that the mineral matter amounts to much the same as that contained in Dutch cocoas, in which it is admitted that certain salts are used with the object of preventing sediment in the cup. The cocoa is thus more "soluble," that term really meaning that the cocoa is kept permanently suspended in the cup, as a very small proportion of the cocoa is really soluble. One important feature, however, of "Health and Strength" cocoa is that it is an extremely finely ground powder, having, in fact, the fineness of flour. This, of course, is a dietetic advantage. To sum up, "Health and Strength" cocoa differs from most other cocoas in having its nitrogenous constituents increased by the further elimination of fat, and a special method of preparation is adopted by which the cocoa is reduced to an impalpably fine powder.

ANNUAL REPORT FOR 1909 OF THE REGISTRAR-GENERAL FOR SCOTLAND.

THE fifty-fifth report of the Scottish Registrar-General, which has recently been issued by H. M. Stationery Office, contains the usual particulars concerning marriages, births, and deaths during the year 1909, but the tabular matter is prefaced by a useful introduction by Dr. J. Craufurd Dunlop, the medical superintendent of statistics, and it is to this part of the volume that we now propose to direct attention.

The circumstance that considerable delay ordinarily takes place in the issue of the Scottish reports is acknowledged and accounted for in a prefatory note, which explains that as the abstraction of the facts cannot be completed until the expiration of 12 months after the registers are closed, the detailed annual report cannot be issued sooner than 18 months after the close of the year to which it relates.

Recent enumeration of population.—In April last the twelfth Census of Scotland was taken, and since that date the preliminary Census report has been published. The use of the recent population returns in the preparation of the present report has enabled the vital statistics of the year to be presented with greatly increased confidence. A prominent feature of these statistics is the lowness of the rates of marriage, birth, and death, as well as of infant mortality. The birth-rate, the death-rate, and the infant mortality-rate were in each case the lowest on record, and with the exception of that of the years 1886 and 1887 the marriage-rate of 1909 attained its lowest point.

Declining birth-rate.—Calculated on the revised population estimate, the Scottish birth-rate averaged 27·33 per 1000 living, which is the lowest rate hitherto recorded, and is lower by 1·63 than the mean rate in the preceding decennium. The birth-rate of Scotland was above that of England by 1·7 per 1000, and above that of Ireland by 3·8 per 1000. In the principal towns the birth-rate ranged from 37·9 per 1000 in Motherwell and 36·7 in Hamilton, to 25·9 in Kilmarnock. In some of the counties the rate was very low; it did not exceed 18·4 in Selkirk, 17·3 in Bute, or 17·2 in Orkney. The illegimate birth-rate, expressed in terms of unmarried and widowed women between the ages of 15 and 45, averaged 14·1 per 1000, and varied from 29·6 in Banff, and 24·3 in Wigtown, to 8·2 in Renfrew and 7·2 in Orkney.

Reduced mortality.—The general death-rate of Scotland in 1909 was 15·85 per 1000, this being the first year on record in which the rate had been below 16 per 1000. The rate was below the average of the preceding ten years by 1·29 per 1000. In the Scottish counties the crude or uncorrected death-rate ranged from 17·5 in Lanark to 11·3 in Peebles. The death-rates of the principal towns, corrected for age and sex differences of population, ranged from 21 6 in Glasgow and 19 7 in Dundee, to 13·4 in Motherwell and 12·8 in Partick.

Infantile mortality.—The deaths of infants in their first year of age were in the proportion of 108 per 1000 births, which is the lowest rate hitherto recorded, and is below the mean decennial rate by 12·8 per 1000. In the Scottish counties infant mortality ranged from 132 in Kinross, 124 in Lanark, 122 in Forfar, and 121 in Aberdeen, to 58 in Shetland, 53 in Sutherland, 49 in Peebles, and 48 in Argyll. In the principal towns infant mortality was still very high, being equal to 152 in Aberdeen, 145 in Dundee, and 133 in Glasgow.

Causes of death.—Of the total deaths registered during the year the causes were certified either by the medical attendant or by a procurator fiscal in all but 2 1 per cent. Letters of inquiry were addressed to medical certifiers in those cases where the causes were insufficiently described for purposes of classification. As a result we learn that of the deaths originally referred by classification in the certificates either to intestinal obstruction or to tumour or other indefinite cause, not fewer than 95 were eventually assigned in the registers to malignant disease. In addition to the foregoing much valuable information has been secured by means of these inquiries, and Dr. Dunlop gratefully acknowledges the coöperation of his medical brethren in this portion of his work.

Tuberculosis.—A satisfactory feature of the vital history of the year is the continued decline in the mortality from tuberculosis of all forms, as well as from tuberculous phthisis, the rates under both these headings being the lowest hitherto recorded. The death-rate in 1909 from all forms of tuberculous disease was 198 per 100,000 living, 128 of that number being due to phthisis. Previous to 1886 the Scottish death-rate from phthisis was always above 200. In 1887, for the first time, it fell below that figure, whilst in 1909, for the first time, it fell below 130. The male death-rate from this disease was 136 and the female rate 121. Of those dying from phthisis, 85 per cent. were between the ages of 15 and 60 years, whilst only 3 per cent. were below 5 years and only 6 per cent. above 60 years of age. Disregarding sex, phthisis mortality ranged from 146 per 100,000 in the insular-rural districts to 117 in the small town districts. Among the principal towns phthisis was fatal in the proportion of 176 per 100,000 in Dundee, 152 in Glasgow, and 145 in Paisley, whilst it was fatal to 89 only in Partick, 73 in Motherwell, and 58 in Kirkcaldy.

Epidemic disease.—Comparing the death-rates from the principal epidemic diseases in the year under notice with the corresponding rates of former years, we note that the marked difference between the deaths from "fevers" in 1909 and those in the three years immediately preceding is largely due to the subsidence of the epidemic of cerebro-spinal fever which prevailed in those years. Typhus fever seems still to linger in certain parts of Scotland, as appears from the fact that 26 deaths from that disease occurred in the course of the year under notice, a number which exceeds the quinquennial average by 8. The increase of these deaths was due to an epidemic in the fever hospital at Greenock, in which town 16 of the 26 deaths took place. The mortality from enteric fever did not differ greatly from the quinquennial average and was equivalent to a rate of 6 per 100,000 living. The mortality from scarlet fever and from diphtheria was relatively high and that from measles and diarrhœa relatively low. The death-rate from malignant disease was higher than in any previous year, and for the first time exceeded 100 per 100,000 of the population. The mortality from pneumonia and from bronchitis scarcely differed from the normal.

A chapter on the influence of weather on mortality concludes this very instructive report.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 25, 1911.

The National Insurance Bill.

As we go to press a special meeting of the Representatives of the British Medical Association is being held in London to which a report of the Council of the Association upon the National Insurance Bill has been submitted. The meeting had its origin in a resolution passed at the annual meeting of Representatives at Birmingham which provided that, upon the completion of the Committee stage of the National Insurance Bill, the Council of the Association should issue to the divisions a report upon the position under the Bill as amended, and should convene as soon thereafter as practicable a special meeting of Representatives to consider the matter. Remembering the position in which the Bill now stands after the treatment which it has received since the summer meeting of the British Medical Association, we may take it for granted that the proceedings of the meeting now being held will be arduous, protracted, and important. For the Representatives are placed, in considering the particular sections of the Bill which affect most closely the medical profession, in exactly the plight of every class of the population in considering those clauses of the Bill in which they believe themselves to have important concern. They must feel in doubt of their ground. Since the Representatives last had the Bill under discussion a large number of complicated amendments have changed the face of the document in many essentials as well as in countless details, while the procedure which has been adopted in Committee of the House for dealing with these amendments has not allowed of adequate discussion. The very meaning of some of the clauses which the Representatives are considering has not been threshed out, much less has their bearing on life, when the Bill becomes law, had adequate consideration. The report which has been submitted by the Council of the Association is confidential while we write, though its bearings will probably have become public property by the end of the week. Even if we felt ourselves at liberty to comment on this report in the favourable terms which we should certainly be moved to do, it is our duty to respect the fact that the document is still confidential, while no public service would be rendered, at a time when all medical men are agreed in attempting to find a unanimous course of action, by any interjections during the meeting of the Representatives of the British Medical Association.

The essential position remains unchanged and was well shown at an enthusiastic meeting of the medical profession held in Manchester on Saturday last, Nov. 18th, when the following resolution was unanimously carried:—

That in the opinion of this meeting the National Insurance Bill as at present framed does not satisfactorily embody the demands of the medical profession, as defined in the "six cardinal points" formulated by the British Medical Association; that the scheme of the Bill in its present form is unworkable, and will create a condition of affairs not only detrimental to the medical profession, but also dangerous to the public health—therefore, this meeting of the medical profession of Lancashire and Cheshire expresses its determination, in the event of the Bill becoming law in its present form, to unite with the whole of the profession in declaring its inability to undertake the duties which the Bill proposes to assign to it.

This resolution is the deliberate opinion of a large mass of medical men who were determined, before it was too late, to register their opposition to the Bill and their dissatisfaction with the course of the negotiations that had taken place, and, in short and in their own words, who felt "that the scheme of the Bill in its present form is unworkable." The meeting, as Dr. E. S. REYNOLDS in moving the above resolution pointed out, was in no way antagonistic to the British Medical Association, but would strengthen that body in proceedings the value of which had been so fully recognised by all; and with every word of Dr. REYNOLD'S stirring but well-reasoned speech we are in complete accord. In this Bill for national insurance against sickness and invalidity provisions are introduced completely revolutionising the professional, and perhaps the scientific, position of a body of men without whose coöperation the word insurance means nothing at all. Immediately upon the text of the Bill being available the facts were made clear to the Chancellor of the Exchequer by the solid opinion of the medical profession, reinforced by the acquiescence of thinking men and women not medical practitioners and having only one thing in common—personal acquaintance with the conditions of medical practice, including those of medical and scientific education and of hospital administration. As one result of this general feeling that the Bill, however noble in intention, was bad in many of its provisions, six cardinal points upon which amendment was required were submitted to the Chancellor by the British Medical Association. No adequate reply from the Chancellor has resulted. We do not suggest that no concessions have been made in respect of certain of the six points, but the value of the concessions has been minimised by future amendments to an extent which was probably beyond the appreciation of Parliament owing to the pace at which the business in Committee has been conducted and to its complicated nature.

Dr. G. A. GIBSON points out in an eloquent address on the Medical Aspects of Some Social Questions, which we publish in another column, that criticism of the National Insurance Bill is rendered difficult by the sympathy which all medical men must have for most of its declared aims. This it was which led medical men with the rest of the country, upon the introduction of the Bill, to welcome it as an attempt to lead a large proportion of our population to make provision against the accidents of life, a provision which, as Dr. GIBSON says, has notoriously been left unmade in the past. But anyhow the time for criticism of the Bill has gone by and the hour has arrived when medical men must make up their minds whether they will or will not assist in carrying out the Chancellor's scheme. No medical man who opposes this scheme need feel that he is standing in the way of social progress for selfish reasons; he can still remain, what the medical man has always been and must always be, an ardent advocate of every movement that will lighten the

tax upon our population of sickness and invalidity, that will bring solace to the suffering, and security to the workman. Generations after generations of medical men, in a manner which has fallen to the lot of no other body of our community, have shown by actions, not by words, the self-sacrificing pleasure and unremitting zeal with which they attempt to deal with the evils that are designed to be removed by this Bill. Men of such a temper do not change. Our high ideals remain as high, and because this is the case we are bound to set our faces against a measure which, as it stands, does not give to the individual efforts of medical men a common principle by which they can abide. The Bill appears bound in its present state to lead to a deterioration of medical practice, to a falling off from our scientific standards, and to grave interference with medical charities.

Compulsory Notification of Pulmonary Tuberculosis.

IN 1908 the Local Government Board issued regulations rendering compulsory the notification of all cases of pulmonary tuberculosis occurring amongst the inmates of Poor-law institutions or amongst persons under the care of district medical officers. In March of this year further regulations were made extending the system of notification to cases occurring amongst the in-patients or out-patients at hospitals, or other similar institutions for the treatment of the sick, which are supported wholly or partially otherwise than by the contributions of the patients and otherwise than from rates and taxes. The results obtained by these regulations have evidently proved satisfactory in the opinion of those who are able to judge of the working of compulsory notification amongst the classes of patients involved, for new regulations have now been issued completing the system of notification. Hereafter it will be the duty of every medical practitioner, with certain exceptions specified in the regulations, to notify every case of pulmonary tuberculosis occurring in the course either of his public or of his private practice.

The primary object which the Local Government Board has in view in requiring compulsory notification of every case of pulmonary tuberculosis is to enable the local authority to assist in the eradication of the disease, and in a circular letter accompanying the regulations the Board offers certain observations as to the ways in which local authorities can render such assistance. Under the powers of previous Public Health Acts these authorities may either themselves provide sanatoriums or may contract for the use of such institutions. Now the Board has been advised that these powers also enable a local authority to provide or contract for the use of dispensary or out-patient hospitals. Before providing new institutions, it is to be hoped that the charitable institutions already existing in the form of tuberculosis dispensaries will be communicated with; the experience already gained by the officers of these institutions would be of the greatest value, and multiplication of centres is not to be advised. At the same time caution must be exercised not to exploit the services of the honorary staffs of the hospitals, whose duties are already sufficiently heavy. Under the regulations issued in March last some confusion existed as to the procedure to be adopted when a patient suffering from pulmonary tuberculosis passed from one hospital to another, or even from the out-patient department to the wards of the same hospital, as to whether further notification was necessary. In the new regulations this matter is very clearly defined, for the words occur: "..... a medical practitioner shall not be required under these regulations to notify any case of pulmonary tuberculosis which has already to his knowledge, under these regulations or under the Poor-law regulations or under the hospital regulations, been notified to the medical officer of health for the area within which the place of residence of the patient is situate." Useful information is given by the Board as to the limitation of the scope of the regulations. Nothing in the regulations, we learn, shall apply to, or impose any duty or obligation upon, any medical practitioner acting in his capacity as medical examiner of candidates for some office or appointment as medical examiner on behalf of an insurance company of a person proposing to insure his life at the risk of that company, or as medical examiner of the passengers and crew of an emigrant ship. These are wise and prudent exceptions, and being so clearly stated will relieve the responsibilities of practitioners acting under the conditions named. Another important article to which we would draw attention is one compelling every medical practitioner who is a school medical inspector within the period of 48 hours after he has inspected any children attending a public elementary school to complete and sign a notification of all cases of pulmonary tuberculosis of which he became aware during the course of the inspection.

We have mentioned on other occasions the apprehensions which have been expressed of certain hardships which might ensue to individuals as the result of their notification as being the sufferers of a disease so infectious as to require notification, but at the same time we remarked[1] that should the benefits derived outweigh the drawbacks, a far-reaching prophylactic measure will have been established. We have every reason to believe that the views of the Local Government Board have been faithfully carried out at the various institutions coming under the force of the regulations which commenced on May 1st of this year, and we are not aware that any of the personal inconveniences feared have been experienced. All information of this nature imparted to the medical officer of health is, of course, of a strictly confidential nature, and if detrimental knowledge has been conveyed to other quarters, such as the patient's employer, that he is the sufferer from an infectious disease, it would be from other sources than the practitioner or medical officer of health. We are glad to notice that in the circular letter accompanying the new regulations stress is laid by the Board on the fact that the ability to convey infection on the part of patients afflicted with pulmonary tuberculosis is limited and intermittent, and that infection can be prevented by the patient himself when he has learnt and is not too ill to practise elementary precautions. We endorse the statement that the patient may be trained, and may, as a result, cease to be a source of infection, in which case he need be subjected to no disability; therefore we again strongly uphold the contention which we have so often expressed that education must occupy an important place in the campaign against this disease. If

[1] THE LANCET, April 8th, 1911.

by means of compulsory notification patients can be visited by those who are experts in hygiene and sanitary matters, so that they and their surroundings can be fully and satisfactorily controlled and improved, then these regulations will be of true value in helping to stamp out a malady which has already shown such a great diminution in incidence since hygienic improvements have been enforced by law. We may add that the new regulations come into force on Jan. 1st of next year.

Annotations.

"Ne quid nimis."

GUARDIANS AND POOR-LAW REFORM.

WE have had forwarded for our inspection a copy of a memorial from 121 guardians and ex-guardians of the poor presented recently to the President of the Local Government Board. The signatories, who are of both sexes, and who have gained their practical experience in urban and rural unions in all parts of England, are persons whose position, knowledge of their subject, and proved interest in Poor-law administration would alone command respect for their observations, while the matter of their memorial is of considerable importance. It makes no absolutely new proposal, but serves rather as a reminder that the report of the Royal Commission on the Poor-laws and Relief of Distress was issued in 1909 by the majority of a Royal Commission appointed in 1905; that an alternative scheme was propounded by a minority of that Commission who were able to command no less attention for their recommendations than did their far more numerous colleagues; and that no legislative result has followed the reports of either. We are also reminded that Mr. Charles Booth, a Commissioner whose name carries the greatest weight in such matters, unable to take part in the final deliberations of the Commission, propounded yet a third scheme with regard to the question of administration and organisation, advising the grouping of existing unions upon principles which he laid down and the utilisation of existing machinery for carrying out the work of relieving destitution, without those features of the present system which both Majority and Minority agreed in condemning. The memorialists in the present case have evidently in view the scheme of Mr. Booth, and while admitting that the demand for reform is urgent, refuse to admit that a drastic change of areas or the destruction of the present authorities advocated in both Majority and Minority Reports is either necessary or desirable. Their complaint is that shortcomings have been laid at the door of the guardians, the blame for which should at least be shared by the central authority controlling them, and that no fresh principles for their guidance have even now been laid down either by that authority or by Parliament. They ask that questions of principle should take precedence of questions of machinery, and advise that the latter should be deferred until the principles upon which the work is to be done shall have been definitely ascertained. They suggest not unreasonably that any new machinery may in itself be a source of confusion and difficulty in addition to the fact that it will be expected to carry out new measures. They say in effect, "If there is anything new to be done, why do you not tell the guardians what it is and authorise them to do it? Then if you find they are not competent you can appoint an alternative authority to supplement them, but as the matter stands you have not even definitely imposed a policy of universal application with regard to out-relief; you have not done anything with regard to the general mixed workhouse (which you can do by enabling unions to combine and coöperate), and instead of codifying the law which the guardians are still administering, and which they seem likely to continue to administer, you leave for their only guidance a mass of statutes and orders, cumbrous, antiquated, and self-contradictory, which is responsible for much of the confusion of principles that lies at the root of the present difficulty." The points which we have thus summarised are well worth the consideration of those to whom they are addressed. There is an old saying as to threatened men living long. It is possible that the sentence pronounced upon the Poor-law guardians by the Royal Commission will not be carried out, for its execution has now been long postponed. If, however, we carry the analogy further, we must urge that the reprieved convict in justice should be given full opportunity for reform and for leading a better life. The guardians have a just cause of complaint as long as defects in the system which they administer are made a subject of public contempt without their being directed or even empowered to remedy them by the central authority responsible for their guidance.

LICKING STAMPS.

IN an age which has reached high sanitary standards with an obvious improvement in the public health, the licking of stamps is a retrograde proceeding, and any suggestion calculated materially to encourage or increase the habit is open to strong condemnation. The habit is opposed to a common sense of cleanliness, let alone what bacteriological requirements may teach. The speed of modern life, it is to be feared, forces upon us the breaking of many sanitary commandments, and hygienic considerations are made to retire in favour of methods of convenience and despatch. The adhesive stamp is a sanitary blunder, but it is a business convenience for which it is hard to suggest an alternative. No persons need lick a stamp if they seriously make up their minds never to do so, but unfortunately the use of stamps has created a habit which, once contracted, is difficult to avoid. The habit of licking stamps is, in fact, practically universal, and few people consider it an offence against good manners. There are several devices which are intended to obviate the licking of a stamp, but their adoption is comparatively rare. It is surprising to us that the resources of the inventor have not suggested something fulfilling the office of a stamp, but not open to hygienic objections. We are prompted to raise these considerations in view of the provision in the National Insurance Bill which requires the servant and master weekly to affix a certain number of stamps to a card which is left for the inspector to examine. It is fairly certain that the process of attachment will generally be done by licking the stamp. It is no defence to say that already, apart from this new legislative requirement forced upon the household, people are confirmed in the objectionable habit. The proposal obviously broadens the chances of disease being spread in this way, and definite cases of disease have been traced to it. It will be interesting to learn the medical officer's attitude when he finds cards of licked stamps in the houses in which there is infectious disease. No one can deny the extreme convenience and ease of collecting a tax in this way, but there are clearly grave objections to it upon the score of health preservation; and until it is shown that the habit of licking the stamp has died out the objection will always remain, whatever political party it may be which encourages it. Licking envelopes is equally objectionable, and it is time that

human ingenuity found a convenient way of sealing a paper cover or of attaching a stamp which shall not require the aid of the saliva.

THE NORMAN KERR MEMORIAL LECTURE.

UNDER the auspices of the Society for the Study of Inebriety, the fourth Norman Kerr Memorial Lecture was delivered on Nov. 14th in the lecture theatre of the pathological department, Medical Schools, Cambridge. The President of the society, Dr. T. B. Hyslop, was in the chair. The lecturer, Professor G. Sims Woodhead, took as his subject "The Influence of Alcohol on Body Temperature and on the Heart." In commencing his lecture Professor Woodhead pointed out the propriety of the arrangement that the Society for the Study of Inebriety should take charge of a memorial lecture given in honour of the late Dr. Norman Kerr. The society was founded by Dr. Kerr in 1884, and presided over by him until the day of his death. He had, by his researches and writings, taken a very prominent part in calling attention to the need for study of the physical ills resulting from the immoderate use of alcohol. Along with his friend, Sir Benjamin Ward Richardson, Dr. J. J. Ridge, and other workers, he had striven most earnestly and assiduously to place knowledge of the effects of alcohol on the human body on a more satisfactory basis than any on which it had hitherto rested. His was early pioneer work; but all of it was honest, and much of it had stood the test of time and experience. One of the great claims that could be made for him was that he endeavoured to indicate lines along which further researches might be made; and, whatever might be the ultimate finding of physiologists in regard to what may be called "physiological doses" of alcohol, there could be now little difference of opinion as to the action of excessive doses of alcohol in preparing for, initiating, and fomenting disease. The lecturer pointed out that the three former Norman Kerr Memorial lecturers had broken away from the usual method of experimentation and had tried to eliminate subjective phenomena, those phenomena dependent upon the psychical or mental condition of the patient; and he, turning his mind to some line of work in which the evidence might be simply objective, had decided to follow up, if possible, the action of alcohol upon the heart as recorded by the electrocardiographic method. After giving an account of Waller's and Einthoven's work, and pointing out some of the difficulties associated with the method of investigation, he described some experiments carried out upon himself, indicated some of the difficulties with which they were at once confronted, and then showed a series of tracings obtained after the exhibition of various drugs. The action of these drugs was tested, because they had to look upon alcohol as a drug of unknown physiological action, and before they could accept records as indicating any special kind of alteration in the heart they must have records of changes brought about by drugs that had a very definite and well-recognised physiological action. Indeed, although he and Dr. F. Shillington Scales had obtained certain features in the alcoholic record that distinguished it from the non-alcoholic, he was not at present prepared to place too much stress upon this difference or to attempt to interpret its exact significance. Still, bearing in mind the fact that those who had wide experience maintained that the cardiogram of any person was almost as characteristic as were his finger-prints, any deviation from the normal, however slight, might possibly have to be accepted as an indication of well-marked altered conditions. The lecturer then described the late Dr. Arthur Gamgee's apparatus for obtaining continuous records of the temperature of the body, both surface and internal. He pointed out what an immense amount of ingenuity had been put into this apparatus, and regretted deeply that Dr. Gamgee had not lived to finish his experiments, which promised to be of enormous value to the study of disease. He referred also to the admirable work done in this country by Professor Callender and the Cambridge Scientific Instrument Company, and by Messrs. Siemens in Germany. He then threw on to the screen a number of tracings obtained from individuals who had taken some half ounce (15 c.c.) of absolute alcohol. He showed three pairs of curves in which the surface and rectal temperatures were taken at the same time—before, during, and after this dose of alcohol had been administered. In each case there was a distinct rise of the surface temperature as taken in the axilla, and a simultaneous and distinct fall of the visceral temperature. This was interesting, because in the same series of records taken for periods of 24 hours there was, when food was taken, a fall of the surface temperature and a simultaneous rise of the visceral temperature. When hot fluids were taken there was, however, a sudden rise of the surface temperature and an equally sudden rise of the visceral temperature. This, however, in both cases was of short duration. The lecturer pointed out the difficulties that had attended his earlier experiments, and said that whilst perfectly satisfied with some of the results obtained, he should, of course, repeat the whole of the series on a much extended scale. He thought, however, that these were sufficiently interesting to place before the society in this lecture.

THE ETIOLOGY OF OCCUPATION NEUROSIS AND OCCUPATION NEURITIS.

IN the *Journal of Nervous and Mental Disease* for August Dr. W. E. Paul, of Boston, U.S.A., discusses the vexed question of the etiology of the occupation neuroses, and avows himself a staunch supporter of the peripheral theory of their causation. The generally accepted view of their dependence on central—i.e., cortical—disturbance of function is based apparently on the occurrence of cases in which the neurosis is strictly confined to the performance of a particular act. If writer's cramp be taken as an instance, it is only when the fingers pick up a pen or a pencil that the cramp appears; for all other movements or combinations of movements of the fingers, however delicate, muscular action remains unimpaired. Such cases, however, are rare compared with the number in which the defect of function has spread to the performance of more than one special act. The late Dr. Vivian Poore strongly combated the central theory, alleging that he had never seen the writer's cramp of the text-books in which failure of writing power is the sole symptom. In 60 out of 75 tabulated cases he noted loss of function other than writing. Dr. Paul has studied 200 cases of occupation neurosis from the out-patient department of the Massachusetts General Hospital with a view of learning the character of the symptoms and thereby making inferences bearing on the etiology. In no fewer than 177 cases pain is specifically referred to; it was often severe and interfered with sleep. In 72 cases the pain was referred to joints, the shoulder, elbow, and wrist joints being those mainly affected. In only four of the 200 cases did the symptoms point to involvement of any of the main nerves of the limb. It may therefore be said that the preponderance of the pain symptoms is on muscles, joints, and regions near joints, their association with definite peripheral nerves being minimal. Now, if there is an increase in subfascial pressure during muscular contraction, varying with

the duration and power of that contraction, it is quite conceivable that the mechanical effect on the included nerve structures may be, under certain conditions, injurious. Further, the pull on tendons, fasciæ, and ligaments during muscular action may again, under certain conditions, produce mechanical disturbance of nerve function. The sensations of aching, numbness, stiffness, and fatigue that accompany these neuroses, the disagreeableness of which to the patient is out of all proportion to the vagueness of his description, may very well be associated with implication of minute nerves in some of these ways. Dr. Paul does well in calling attention to cases diagnosed as occupation neurosis where the existence of actual mechanical pressure on nerves has been established by rad ography or otherwise. Poore quotes a case diagnosed as writer's cramp in which the symptoms were found to have been occasioned by the pressure on certain nerves of a small aneurysm. Dr. Paul refers to a case of pianist's cramp treated as such for some months in which the patient was subsequently found by the X rays to have a needle buried in the hand. Reference was made a short time ago in these columns to a case of cramp in a typist and shorthand writer where the symptoms were associated with stretching of brachial nerves from an abnormal first rib. It is clear that all cases of occupation neurosis demand the fullest investigation from an objective standpoint ere they can be relegated to the category of neurosis of central origin.

EPSOM COLLEGE.

AN extraordinary general meeting of the Governors of Epsom College was held at the office, 37, Soho-square, W., on Nov. 15th, when the treasurer, Sir Henry Morris, occupied the chair. The object of the meeting was, as has already been announced in these columns, to consider a proposition to delete from By-law 16, Section 1, and from By-law 24, Section 2, the last clause, beginning in each case with the word "Provided," which limited the number of vacancies for pensioners and foundation scholars, occurring within a specified time, that could be filled up from the unselected candidates having the largest number of votes at the previous election. The two sections referred to read as follows:—

By-law 16.—(1) Every vacancy among the Pensioners which shal occur, or shall for the first time come to the knowledge of the Council after any meeting which shall have determined the number of vacancies to be filled up by election at the next Annual General Meeting, and before the expiration of three months after such election, shall, subject to the provisions of this By-law, be filled up by the appointment thereto of the unsuccessful candidate who had the largest number of votes at such election, and who shall not have been previously appointed to a Pension under this section, and every candidate so appointed to any such vacancy shall be deemed to have been elected thereto at the then last preceding election, but his Pension shall not commence until the date of his appointment: Provided that the number of vacancies filled up under this section after any one election shall not exceed three.

By-law 24.—(2) Every vacancy among Foundation Scholars which shall occur, or shall for the first time come to the knowledge of the Council after any meeting which shall have determined the number of vacancies to be filled up by election at the next Annual General Meeting, and before the expiration of four months after such election, shall be filled up by the appointment thereto of the unsuccessful candidate who had the largest number of votes at such election, and who shall not have been previously appointed to a Foundation Scholarship under this section, and every candidate so appointed to any such vacancy shall be deemed to have been elected thereto at the then last preceding election: Provided that the number of vacancies filled up under this section after any one election shall not exceed three.

The chairman stated that before the alteration of the by-laws 16 years ago all vacancies for pensionerships and foundation scholarships occurring within three months after the election could be filled by the admission of those unsuccessful candidates who had received the largest number of votes. Under the present by-laws, however, not more than three vacancies in each class could be so filled, the limit of the period after the election being three months in the case of pensioners and four months in the case of foundation scholars. As the pensioners were for the most part advanced in years it was exceedingly probable that a number of vacancies might occur between the date of the April council meeting, when the voting papers had to be printed, and three months after the annual general meeting, which is held about the end of June, whilst in the case of foundation scholars it was difficult for the head-master and the bursar to estimate so early as in April the number of boys who would be leaving the college within four months after the election. Moreover, when making appeals for subscriptions and donations the council had for many years stated that 50 pensioners and 50 foundation scholars were being maintained by the foundation. Consequently, if more than three vacancies in either class occurred the council were not, strictly speaking, keeping the promise held out to persons as an inducement to them to subscribe. If the proposed amendments in the by-laws were adopted by the Governors, the council would be enabled to insure that at the beginning of every school year there were on the books of the college the full numbers of 50 pensioners and 50 foundation scholars. The requisite resolution to the effect that the last 19 words be deleted from each section was then put to the meeting and unanimously carried, as might have been expected from the unanswerable arguments for the reform advanced by Sir Henry Morris.

THE VOLUNTARY AID DETACHMENTS FOR WAR TIME.

THE necessity for the formation of voluntary aid detachments for sick and wounded in time of war has been fully recognised by those who have seen the horrors of warfare. A scheme for the organisation of voluntary aid in England and Wales has been promulgated by the medical division of the War Office on lines suggested by Sir Alfred Keogh, formerly Director-General of the Army Medical Staff. It has been arranged on lines similar to those followed by certain foreign countries, where organisations for the relief of sick and wounded have reached a high standard of efficiency. The number of voluntary aid societies and associations which already exist, having no connexion with each other, leave them liable to act independently, with the result that their respective spheres of action might not be so coördinated and kept in touch with each other as to render their services of the greatest value in time of war. A county system has accordingly been adopted, because that is the one upon which the Territorial Force is organised and which the British Red Cross Society also has adopted as the basis of its constitution. Voluntary aid detachments, as organised in each county, comprise two classes—men's detachments and women's detachments. The men's detachment consists of a commandant, preferably a retired officer of the army not liable to recall, one medical officer, one quartermaster, one pharmacist, four section leaders, and 48 men, forming four sections of 12 men each. The women's detachment comprises a commandant (man or woman, not necessarily a doctor), one quartermaster (man or woman), one qualified nurse as lady superintendent, and 20 women, of whom four should be qualified as cooks. In the training of these detachments a practical knowledge of improvised methods of aid is an essential feature. The detachments will have no depôts of stores to draw upon in the event of mobilisation; all their requirements and equipment will have to be collected and, for the most part, improvised by the detachments themselves. Up to the present there has been considerable difficulty in the way of detachments acquiring information upon this subject, as no official or other handbook has existed dealing fully and systematically with such details in the English language. There are, of course, many handbooks on first-aid treatment, but these do not cover

the subject from the point of view of the present "Voluntary Aid Detachments," as organised by the War Office. To supply this want Lieutenant-Colonel H. Mackay has compiled a well-written, accurate, and concise little book entitled "Improvised Methods of Aid in the Field,"[1] based on recently delivered lectures to the Wiltshire No. 1 Voluntary Aid Detachment. It should be most helpful to the patriotic men and women who are giving their services to the country by joining the voluntary aid detachments, as well as to members of the Territorial Medical Service. The approval of Sir Alfred Keogh, as noted in the preface, is a strong recommendation. We can heartily commend any well-advised measure likely to stimulate patriotic enthusiasm directed towards the minimising of the due effects of war—which, as history shows, not infrequently breaks out when least expected.

THE OFFICIAL OINTMENTS.

A USEFUL paper on the official ointments was read at the October evening meeting of the Pharmaceutical Society. The authors, Mr. R. G. Guyer and Mr. W. T. Ewing, in the course of their observations, remarked that up to the present time no definite information had been published concerning the power of the skin in absorbing ointment bases. Dr. F. Gardiner, however, who has been working in the Research Laboratories of the Royal College of Physicians, Edinburgh, has made a study of the preparation of ointments, and allowed Mr. Guyer and Mr. Ewing to anticipate the publication of the full details of the experiments by utilising some of the results. In determining the relative penetrative power of various ointment bases, Dr. Gardiner's procedure was to rub the base, to which a dye had been added, into a given area of a guinea-pig, for a given length of time, and to kill the animal and make microscopical sections of the part. The degree of penetration was observed by the depth of staining on the hair-root, and Dr. Gardiner's observations show that olive oil is the most absorbable of the official substances, the others coming in the following order: benzoated lard, anhydrous wool fat, hydrous wool fat, and petroleum jelly. As showing the important place which ointments take in medical treatment, it may be mentioned that a recent survey of 4000 prescriptions gave evidence that practically 10 per cent. were for ointments only. In the practice of medicine ointments have undergone considerable change during the past few years; they are now seldom used for surgical purposes, but as a result of the development of dermatological medicine their use in this connexion has increased considerably. In a criticism of the various ointment bases the authors stated that olive oil and almond oil are very useful in preparing certain creamy bases, especially those which are to form a vehicle for an oleate, and also those cases in which absorption is of paramount importance. For general purposes, however, they are not to be recommended owing to their tendency to form fatty acids. Lard, although a most useful base for strictly emollient ointments, is receiving distinctly less and less support in dermatological practice owing to its tendency to irritate the skin, the irritation being due most probably to the production of fatty acids. Spermaceti is decreasing in use and is chiefly employed to give the finished article a crystalline appearance and to raise the melting point. As to the paraffin bases, the authors said that in many respects these were ideal, and wool fat has become established as a reliable and highly important ointment base. The demand for some of the official ointments, notably capsicum, eucalyptus, lead iodide, potassium iodide, lead carbonate, sulphur iodide, stavesacre, calomel, and red iodide of mercury, is very small, and the question may rightly be raised whether the retention of these ointments in the Pharmacopœia is justified.

[1] Improvised Methods of Aid in the Field. For the Use of Voluntary Aid Detachments and Members of the Territorial Royal Army Medical Corps. By H. Mackay, M.D., T.D, Lieutenant-Colonel R.A.M.C.T., Commanding 1st S.W. Mounted Brigade Field Ambulance R.A.M.C., London: Eyre and Spottiswoode, Limited. 1911. Pp. 112 + viii. With two diagrams in colours and 45 illustrations. Price 1s. 6d. net.

THE CHEMISTRY, PHYSIOLOGY, AND ÆSTHETICS OF A CUP OF TEA.

IN our next issue we propose publishing a concluding article upon this subject. Our readers may remember that a previous article was published in THE LANCET of Jan. 7th, 1911. In that article we announced that further researches were proceeding in our laboratory, the results of which would be published as soon as they were completed. A good deal of work has since been done, and the results are of interest. They refer to caffeine tannate as the therapeutically important constituent of tea infusion; the preparation and composition of caffeine tannate; caffeine tannate physiologically considered; the effect of over-infusing tea; blends, and the behaviour of tea with different waters. The report contains a description of the methods of analysis employed, which show a departure from the methods hitherto published, and which are regarded as being instrumental in throwing fresh light upon the question.

TRIBALISM AND QUACKERY.

IT is a commonplace to maintain that quackery is on the increase, but, on examination, this appears scarcely true. Quackery dates from pre-historic times, and is, indeed, a survival of the magic of the tribal medicine-man. Anciently, as anthropologists have pointed out, the tribe was dominated by medicine-men, who were, in some sort, the fount of priesthood, kingship, and the governing classes. At an early date the human conscience began to develop and the medicine-men themselves grew first honest, then honourable, and finally scientific. But quackery, which still dominates hosts of uneducated minds in all classes, is none the less a survival from the tribal condition. It savours of the days of lacustrine man. When, as in recent years, we may behold in what might be called the most cultivated part of London, a large shop window full of "rheumatic rings"[1] at 7s. 6d. each we exclaim against the increase of superstition. There is no increase evidenced, we are only looking at a comic survival. There was a long time in human development when rings were worn as amulets. Considerably more than 1000 rings have been recovered, for example, by antiquarians from the known Bronze Age settlements, and it would be at least rash to suppose that all these were merely worn as ornaments by a necessarily rough-handed generation of archaic men. Be that as it may, it is known that rings were regarded in the Middle Ages as having magical and protective powers. Tribalism, as we may call the tribal heredity of races accounted civilised, assuredly explains many disturbing phenomena. Certain classes are tribal, static, instinctively adherent to a remote social past, and this to a degree most perplexing to those reformers and educationists who believe that every class is potentially the same as every other class. In her delightful remarks upon "the simple savage and his simple life" Miss Beatrice Grimshaw ("The New New Guinea," 1910) says of the Papuan cannibal that "His medicine is sorcery pure and simple. He shuts out every breath of air from his hut if he can manage to do so, and washes only when he is caught out in the rain." Perhaps alone among

[1] In Paris "migraine rings."

modern travellers she insists on the personal filthiness of low savages. Now, filth and airlessness are flourishing traditions among those belated barbarians, the proletarians of Europe. Phthisis, venereal disease, and, indeed, insect-borne and zymotic disease of every kind, are palpable relics of the airless and unwashing customs of savagery. Phthisis descends from the closed hut of the primitive man—it is still combated behind closed windows among primitive Celts. Venereal disease, spread, it may be, by the dissolute males of all classes, has certainly been nursed and incubated by the dissolute females of the classes that do not wash.

AN AVOIDABLE ACCIDENT DURING LUMBAR PUNCTURE.

IN the *Journal of the American Medical Association* of Oct. 14th Dr. W. F. Lorenz has reported a case of an avoidable accident during lumbar puncture—breaking of the needle by a movement of the patient. This he had long expected, but it did not happen until he had performed a large number of lumbar punctures. The patient was in the lateral position on the left side fully flexed. He was held in this position by an attendant with one arm beneath the patient's knees and the other about his neck. Ethyl chloride was used as a local anæsthetic. The puncture was made in the fourth lumbar interspace, just to the right of the median line, and close to the upper border of the fifth spinous process. The patient did not appear to heed the entrance of the needle, but when the point was in the neighbourhood of the canal he suddenly extended his back and the needle snapped, leaving four centimetres well below the cutaneous surface. He was immediately anæsthetised, and a search made for the needle without success. Three days later a skiagram was taken, and showed the needle lodged close to the upper border of the fifth lumbar spine. The patient was again anæsthetised, and the needle was easily removed. Dr. Lorenz points out that this accident can be prevented if means are taken to prevent a sudden extension on the part of the patient. For this purpose he now employs a light padded stick placed beneath the patient's knees which is attached by means of light straps to canvas bands coming over the shoulders and beneath the armpits. The bent knees can be drawn as close to the trunk as is desired, producing complete flexion of the spine. This is desirable for successful puncture. The appliance makes sudden extension on the part of the patient impossible. The difficulty in finding the fragment of needle, although its approximate position was known, is remarkable. This emphasises the help of skiagraphy, which showed the needle plainly in its relation to the spine as well as its depth below the cutaneous surface. The patient experienced no ill results from the presence of the fragment of needle; from the accident until the time of its removal he was up and about.

HUMIDITY AND HEALTH.

THOUGH many observations on the influence of humidity in disease are scattered throughout medicine and the subject has received special attention from climatologists, our knowledge of it is empirical rather than scientific. In its discussion we are confronted at the outset with the difficulty that humidity is used in two senses—absolute and relative. By absolute humidity is meant the amount of water in the air per cubic foot; by relative humidity, the percentage that this water is of the amount which the air can hold at the same temperature when saturated. The hotter the air the greater the amount of water required to saturate it. In the *Boston Medical and Surgical Journal* of Sept. 7th Dr. P. W. Goldsbury has published a suggestive paper on humidity and health. Though it is based on American conditions, climatic and domestic, which are very different from those of this country, his conclusions have a general application. He points out that air saturated with moisture at a temperature of 70° F. contains 8 grains of water to the cubic foot, while saturated air at 18° contains only 1 grain. Thus, if in winter with an atmospheric temperature of 18° saturated with moisture a flat be heated to a temperature of 70°, the air of the rooms, while having the same absolute humidity as the external air, will have a relative humidity of only one-eighth or 12½ per cent., as against 100 per cent. outside. Similarly, if the outside air contain half a grain of water to the cubic foot, and therefore has a relative humidity of 50°, the air of the rooms will have a relative humidity of 6¼ per cent. Now if it is remembered that a humidity of from 60° to 75° is none too much for the average conditions of human life, it will be realised how far different is the humidity of the air in which people are often housed in winter. Dr. Goldsbury finds that in schoolrooms, hospitals, and living rooms during winter the relative humidity is often below 40° and sometimes as low as 10°. Under such conditions indoor air is very dry and irritating. Dr. Goldsbury regards it as one of the prime causes of chapped hands and parched lips. To its injurious effect he ascribes the bad complexions of American women, while to the moister atmosphere and less indoor life he attributes the fresh complexion of English women. We may add that the still fresher complexion of Irish women who live in a still moister atmosphere bears out his contention. For the same reason the southern coast cities are famed in the United States for the complexions of their women. The problem of moistening heated indoor air so as to approximate its relative humidity to the more natural level of outdoor air has received little attention. Means to this end are growing plants, which give off a good deal of moisture from their leaves, porous vessels filled with water, and the placing of receptacles containing water over stoves or other sources of heat. It must not be forgotten that in some conditions, such as rheumatism, dryness of air, not humidity, is desirable.

THE TREATMENT OF INFANTILE PARALYSIS.

WE have received from Dr. William Mackenzie of Melbourne two pamphlets[1] dealing with the treatment of infantile paralysis in which some original and heterodox views are expressed. Dr. Mackenzie is of opinion that the muscular factor has been largely overlooked in the pathology of the disease, and he directs his treatment especially to the muscles. He appears not to be convinced that the chief lesions of the disease are in the anterior cornua of the cord, and even suggests that these may be late sequels of the muscular changes. He objects to the treatment by massage and electricity while waiting for the recovery of the anterior cornual cells. He affirms that every affected muscle will work if a commencement be made from what he defines as the "zero" position, and also that an affected limb will retain its heat and show little wasting provided that it be rested and worked within physiological limitations, even without massage and electricity. By the "zero" position is meant one in which the muscle is as nearly as possible at rest, and therefore one in which the origin and insertion of the muscle are practically on a level and in a straight line. This position is the most advantageous one for the muscle to start its movements, and one from which the weak movements of which it is capable may be increased to more effective ones. Dr. Mackenzie therefore constructs splints adapted to various forms of paralysis, with the object of keeping the muscles in the "zero" position at first. He believes that all muscles,

[1] Treatment of Infantile Paralysis. By William Mackenzie. Melbourne; and Australian Medical Journal, June 20th, 1911.

if seen early enough in the course of the disease, are capable of recovery, and that much improvement can be effected even in old-standing cases. In the latter case, however, division of the deep fascia over the muscles may be an advantage, since it may form a firm, more or less unyielding band preventing enlargement of the muscle. Dr. Mackenzie explains that his method consists in getting the affected muscle to resume work gradually, at the same time counteracting any tendency opposing this, such as the overaction of other muscles. He maintains further that work must not be done for the muscle; it must work up to its capacity at the time, and that by massaging a muscle like the paralysed deltoid with the arm hanging down we are asking damaged cells to work at the greatest disadvantage. In his splint for upper arm cases the arm is held up at right angles to the body and the deltoid is gradually made to move from this position. He gives photographs illustrating the results of his methods. While we find it difficult to accept Dr. Mackenzie's criticism of the current views on the pathology of the disease in the light of recent observations upon epidemic poliomyelitis and upon the experimental disease in monkeys, his methods of treatment certainly seem rational and worthy of trial.

THE result of the voting at the recent election of Direct Representatives for England and Wales is as follows:—

Dr. Henry William Langley Browne	7906
Mr. Thomas Jenner Verrall	7502
Dr. Henry Arthur Latimer	7173
Mr. George Brown	3424
Dr. Arthur Hawkyard	2727
Dr. Sidney Cameron Lawrence	2448
Mr. George Jackson	2182
Dr. Arthur George Haydon	909

By the report of Mr. Norman C. King, the Acting Registrar, which by direction of the English Branch Council has been entered on the Minutes of the Council, it appears that only 51 per cent. of the electorate used their suffrage.

A MEETING of the British Hospitals Association will be held at the Westminster Palace Hotel, London, S.W., on Dec. 1st, at 4.30 P.M., to discuss the National Insurance Bill as it affects hospitals and infirmaries. Hospital managers all over the country have expressed a desire that such a meeting should be held, and Members of Parliament and others interested in the question have intimated their intention of being present.

THE annual Richard Middlemore post-graduate lecture will be delivered at the Birmingham and Midland Eye Hospital by Mr. J. Jameson Evans, surgeon to the hospital, on Thursday, Dec. 7th, at 5 P.M. The subject selected is Toxic Diseases of the Eye, and all qualified members of the medical profession are cordially invited to attend. Clinical cases will be present for observation, and there will be a lantern demonstration.

THE autumn dinner of the Irish Medical Schools' and Graduates' Association will be held at the Hotel Cecil, London, on Nov. 30th, at 7.15 P.M. The President, Sir Charles Cameron, C.B., will be in the chair, and Lord Ashbourne and Mr. R. F. McCall, K.C., will be the guests of the association. Tickets may be obtained from Mr. W. J. Corbett, the honorary secretary of the dinner, at 18, Weymouth-street, Portland-place, London, W.

THE next session of the General Medical Council will begin on Tuesday, Nov. 28th, when the President, Sir Donald MacAlister, K.C.B., will take the chair at 2 o'clock P.M.

ANNUAL REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

TWO interesting reports with reference to the period 1910–1911 have recently been published by the Local Government Board. The first is the report upon Poor-law administration, the second is the report of the medical officer of the Board; Dr. Arthur Newsholme, to the President relating to the public health of England and Wales. We are at the present confining our attention to Dr. Newsholme's report, which discusses many subjects of vital importance to our profession. Having carefully perused this volume, and the introductory letter in which the medical officer summarises his experience of the progress of public health, we may say at once that it forms a worthy contribution to the series of essays on preventive medicine for which the Medical Department of the Board has achieved a well-deserved celebrity. A special feature in the present report is the frequent use of diagrams in place of, or in addition to, the tabular matter that is ordinarily relied on to enforce the teachings of vital statistics. Many readers there are to whom the scrutiny of columns of figures is tedious, if not misleading, but in whom interest is quickly awakened at the sight of aptly contrived diagrams such as those here provided in abundance. We welcome the introduction of this clear pictorial assistance to our intelligence, for however succinctly prepared and clearly written such a document as that under review may be, it must necessarily bristle with details of the sort which can be carried in the memory far easier if their lessons can be visualised.

Dr. Newsholme refrains from discussing in detail the mortality experience of the year, on the ground that this will be fully dealt with in the forthcoming report of the Registrar-General. An interesting survey is, however, given of the movement of the general death-rate in the course of the last 40 years. Comparing the mortality in the last with that in the first decennium of that period, we learn that a fall of fully 20 per cent. has taken place. Had the death-rate of 1910, in an estimated population of 36,000,000, been equal to the average rate in 1891–1900, not fewer than 171,879 deaths would have been recorded in addition to those which actually occurred. Special attention is invited to the behaviour of certain communicable diseases, both among children and adults, as having intimate relationship to immediate sanitary administration. These diseases are here considered in some detail because of their direct bearing on public health work, although the scope of preventive medicine is by no means limited to the diseases alluded to. As in past years, the subject of infant mortality is referred to, but of purpose, and in view of the circumstance that a special report on this topic is now in course of preparation the remarks thereupon in the present report are only brief. There has been in recent years a substantial fall in the infantile death-rate, and collateral evidence points to improvement at the higher ages likewise. The climatic conditions in recent years have certainly been favourable to infant life, but even allowing for this, there is no doubt that much of the life-saving already accomplished is the result of the increased concentration of public attention upon the health of mother as well as child which has been observable of late. During 1910 897,100 births and 94,828 deaths of infants in their first year were registered in England and Wales. If the experience of 1896–1900 had been repeated in 1910 there would have been 45,120 infant deaths in addition to those that actually occurred. Dr. Newsholme's remarks on the loss of life from the diseases and accidents incidental to childbirth, which deserve the attention of sanitary authorities and their officers, may be here conveniently referred to. Puerperal troubles have but a small effect on the figures of infantile mortality, but by as much as they decrease so much must we look to other causes for the annual toll of infants. That the puerperal state involves appreciable risk to mothers is shown by the fact that in one year alone more than 3300 mothers perished from disease or accident peculiar thereto. During the years 1897–1906 the death of 1 mother in every 228 births was thus caused. In 1909 the proportion was 1 maternal death to 270 births, and the ratio is still

decreasing. The rates from "total puerperal mortality" are shown in a diagram which indicates a fall of more than 30 per cent. as between 1901 and 1909. The fall is more pronounced in the case of "puerperal sepsis" than in that of "accidents of childbirth."

Another diagram shows that the highest puerperal sepsis rates are experienced in North and South Wales, and the highest rates from accidents of childbirth in Westmorland. From both groups of causes the rates are lowest in London and in the adjacent counties. "It is not unlikely," says Dr. Newsholme, "that the lower mortality of London and the Home Counties from accidents of childbirth, in comparison with Wales and the outlying parts of England, is partly due to the fact that the latter comprise districts which are sparsely populated or difficult of access, and where consequently emergency treatment is difficult to obtain, and partly to the greater facilities for obtaining institutional treatment or the assistance of consultants in London and its neighbourhood." Ophthalmia of the new-born, although relatively seldom appearing in the records of mortality, is a disease of most serious character, involving as it frequently does, in the absence of appropriate treatment, the total or partial loss of eyesight. Even when medical attendance is available, it by no means follows that the necessary prompt and active treatment will be carried out. The medical practitioner's instructions are apt to be neglected, and perilous delay in treatment is wont to occur. Hence there is need for immediate official supervision. Concerning the administrative methods adopted in those places where the disease is compulsorily notifiable, evidence is being collected and will shortly be published by one of the Board's medical inspectors. Meanwhile there are indications of gratifying success in some districts of existing measures for the prevention of blindness. It is satisfactory to learn that, judging by army and navy experience, the prevalence of gonorrhœa, which is the main cause of ophthalmia in the new-born, is decreasing, while sanitary authorities are in many instances systematically endeavouring to prevent and to cure this disease, which is responsible for so much of the blindness in this country.

The position of infantile mortality enjoys a proper pre-eminence in all comparisons of vital statistics—we are here beginning at the beginning. But, as a standard of sanitary progress, equal importance attaches to the behaviour of enteric fever and tuberculosis. In order to trace the course of mortality from these and certain other diseases average rates are given for four consecutive ten-year periods. Although these average rates conceal variations of annual prevalence, they are convenient for present purposes as indicating the general course of events. In the decennium 1871–80 England lost by enteric fever 33 in every 100,000 persons living; in the decennium ended 1910 the loss was 9 only in the same number living. By the use of a diagram it is shown that between 1901 and 1910 the mortality from this disease fell by not less than 68 per cent. Enteric fever resembles tuberculosis, and differs from scarlet fever and from diphtheria, in this respect, that it shows no marked tendency to changes either of severity or of cyclic prevalence. Since 1869, in which year it was first officially discriminated from other forms of continued fever, enteric fever has shown uninterrupted decline in mortality, and in Dr. Newsholme's judgment this decline is directly traceable to public health work. Last year enteric fever caused 1848 deaths in England and Wales. Had the death-rate been the same as in the period 1871–80 the deaths would have amounted to about 11,800. The saving of nearly 10,000 lives in a single year implies the occurrence of about 70,000 fewer cases of a disabling illness, and a correspondingly diminished loss of national efficiency. It is further calculated that the total saving in respect of enteric fever alone cannot be less than three millions sterling. Prominent among the causes of this enormous reduction of enteric fever prevalence is undoubtedly the general provision of public water-supplies. But that danger still lurks in certain drinking waters is proved by the experiences of Swanage in the autumn of last year when a sharp epidemic occurred as the result of drinking water contaminated with sewage. Next in importance to the maintenance of a safe water-supply comes the provision of a satisfactory system of main sewerage, which, when accompanied by an ample supply of water, permits of the substitution of water closets for privies and middens. The experience of Grimsby, Portsmouth, and other places on the coast illustrates a somewhat frequent mode of infection by the ingestion of polluted shell-fish. Dr. A. Mearns Fraser, medical officer of health of Portsmouth, is quoted as having reported that he possesses a history of hundreds of cases of enteric fever collected during 14 years, which are proved to have been directly caused by eating polluted shell-fish. "In the light of evidence already available," says Dr. Newsholme, "there is reason for believing that much enteric fever, the source of which is still unrecognised, ... will eventually be traced to the consumption of contaminated shell-fish." Infected ice-cream has often been suspected, but seldom proved, to be the cause of enteric fever prevalence. But in the fall of last year 142 cases of that disease occurred in quick succession at Eccles in Lancashire, the cause of which was traced to the ingestion of ice-cream containing typhoid bacilli. We agree with Dr. Newsholme that in accounting for the decline of enteric fever in this country higher importance should be attached to the considerable amount of hospital accommodation now existing for the isolation of persons suffering from that disease. In the year 1890 only 18 per cent. of the known cases in London were treated in the hospitals of the Metropolitan Asylums Board; in the year 1910 the proportion exceeded 40 per cent. A considerable number of cases of this disease are now treated in the general hospitals of the metropolis; and in the chief provincial towns large numbers are annually admitted to hospital for isolation and treatment. A sufficient and acceptable hospital provision for the treatment of enteric fever is now believed to bear an important rôle in the prevention of its recurrence in populous districts.

To pulmonary tuberculosis and other forms of tuberculous infection considerable space is very naturally devoted in this report. The general course of mortality from tuberculous phthisis during the last 40 years is set forth in a table which shows that the English death-rate therefrom in the ten-year period 1871–80 was equal to 219 per 100,000 of the population, whereas in the ten-year period last ended it did not exceed 117 in the same number living. From a diagram it appears that the decrease since 1901 has been continuous. Comparing 1901 with 1909, we find that the death-rate from pulmonary tuberculosis in England and Wales fell by 14 per cent., whilst in the metropolis in the same interval between 1901 and 1910 it fell by not less than 33 per cent. Had the death-rate from this disease been as high in 1909 as the average in 1871–80 the number of deaths in this country would have been 78,308 instead of 38,639, the number actually recorded. Of these 38,639 deaths at all ages 34,414 occurred at ages 15–65, "the working years of life." If Dr. Farr's estimate of the value of a human life (viz., £150) be adopted, the money loss to the community resulting from these preventable deaths was over 5 millions sterling. On a similar calculation a saving of nearly 6 millions sterling was effected in 1909 as a consequence of the fall in the death-rate since 1871–80. Dr. Newsholme concludes this portion of his subject with the following weighty words: "The continuing national loss of health and wealth still caused by tuberculosis is owing in large measure to the fact that local authorities and others concerned have not yet utilised all available means for its prevention," the reference no doubt being to the regulations for compulsory notification shortly to come into force (see p. 1495). In discussing the relative importance of the factors concerned in the recently diminished loss of life from tuberculosis it appears certain, *in limine*, that the latter depends largely on an improved social and sanitary condition of the people. The close relation between bad housing and excessive prevalence of tuberculosis is well known. Not only are the working classes better housed and better fed at the present time than ever before, but their occupations are pursued under far healthier conditions. Increased resistance to tuberculous infection has been secured by these influences, which have also entailed diminished facilities for infection. The more perfect separation of the sick from the healthy has been one of the prominent features of recent sanitation. At the Census of 1901 one in every thousand of the total English population was an inmate of an institution for the sick. In the year 1910 the proportion of deaths from all causes occurring in such institutions was 21 per cent., and in the metropolis it was 43 per cent. The facts

relating to tuberculosis are even more striking. In the year 1910 more than 56 per cent. of the male deaths, and more than 45 per cent. of the female deaths from phthisis occurred in public institutions; and, what is of first importance from a preventive standpoint, the average stay of each patient in these institutions covered the most dangerous period. Recent statistics prove that the death-rate from phthisis has declined in towns quite as rapidly as in the country, and that the urban and rural death-rates from that disease are approximating closely. The circumstance that the phthisis death-rate in towns has improved in spite of relatively inferior housing conditions may perhaps be accounted for by the consideration that the afflicted town dweller can more readily secure hospital isolation and treatment, and that consequently, as compared with his rural comrade, a smaller portion of his sick life is spent in the crowded tenement or cottage.

In one of the appendices the account is given by Dr. Bruce Low, of the prevalence of plague in foreign countries and of its occasional appearance on board ships in our own ports. But in the present report the medical officer draws attention to a small local outbreak of possible human plague in this country not recognisably associated with previous human cases of plague imported from abroad.[1] In October last year four cases of "pneumonic plague" were notified to the Local Government Board as occurring in a rural district of Suffolk. The bacteriological diagnosis of these cases was not confirmed by inoculation tests, but, having regard to subsequent events, it is a reasonable inference that they may have been plague; and there is the further possibility that two previous limited outbreaks of illness in the same neighbourhood may also have been due to this infection. Rat plague appears to have been present for several years in East Suffolk; nevertheless, only three very limited outbreaks of disease suggestive of human plague have hitherto been discovered. Under the conditions existing in East Suffolk human infection must be regarded as an accidental occurrence. The possibilities of spread of plague from rats to man are much smaller in this country than in India. Pneumonic plague spreads readily from person to person, and in two of the outbreaks of suspected human plague in Suffolk the attacks were chiefly of this type. A diagrammatic map is inserted in the report showing the area affected with rat plague and the position of the parishes from which rats were taken for examination. The whole subject is admirably dealt with in an appendix from the pen of that much regretted sanitarian, Dr. H. T. Bulstrode.

We shall return to a consideration of other portions of this report, which is full of information of general interest to the medical profession.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ANNUAL MEETING OF FELLOWS AND MEMBERS.

THE 27th annual meeting of the Fellows and Members of the Royal College of Surgeons of England was held at the College in Lincoln's Inn Fields on Nov. 16th. Mr. RICKMAN J. GODLEE, the President, was in the chair, and he commenced the proceedings by expressing his regret that Sir Henry Butlin had been compelled through ill health to resign the presidency of the College, and he said that he felt sure that all present would join with him in regretting Sir Henry Butlin's absence.

Mr. JOSEPH SMITH moved that an expression of the sympathy of the meeting should be sent to Sir Henry Butlin.

The PRESIDENT then laid before the meeting the annual report of the Council, and he proceeded to comment on some of the matters dealt with in the report. He pointed out that the Council, in reply to a letter from the Registrar-General, had expressed the opinion that it was undesirable that an inquest should be held on every death which occurred after an operation, though they thought that it would be well to mention in the death certificate the fact that an operation had been performed shortly before death. He referred to the action which the Council had taken in reference to the Royal Commission on University Education in London, and he expressed the desire of the Council that the present disability of the London medical student in the matter of obtaining degrees should be removed. With regard to the National Insurance Bill, he mentioned the letter which the Council had sent to the Chancellor of the Exchequer, and the very unsatisfactory nature of the reply which they had received. He next referred to the establishment of a Diploma in Tropical Medicine, and stated that the only candidate had been successful. He also mentioned that though the new Examination Hall would cost £1000 more than they had received from the sale of the old hall, yet they would be relieved of the heavy ground rent of £2200, as the new hall was freehold. The great changes and improvements in the Museum were also mentioned. The President then announced that he was ready for any questions arising out of the report, and that he would answer them if possible.

Dr. S. C. LAWRENCE wished to know how many of the 3627 copies of the annual report which had been sent out had been sent to Fellows, but the President was unable to tell him. Dr. Lawrence also wished to know how many ladies had taken the diplomas of the College. He was informed that four had taken the diploma of Member, but that none had as yet become Fellows. In response to a further query as to the order in which the agenda had been put on the paper he was informed that they were placed in the order in which they were received. A few other questions having been asked and answered,

The PRESIDENT called upon Mr. H. Nelson Hardy to move the first resolution, which was as follows:—

That this meeting of Fellows and Members thanks the Council for its letter of June 1st to the Chancellor of the Exchequer, stating definitely the five points on which, in the opinion of the Council, and in that of the great majority of the Fellows and Members of this College, amendments were required in the Bill; regrets the unsatisfactory nature of the official reply, which subsequent events have shown to be entirely misleading; and trusts that until all those five points have been satisfactorily arranged no Fellow or Member of this College will take part in carrying out the scheme of National Insurance proposed in the Bill.

Mr. HARDY expressed the opinion that the five points mentioned in the letter of the Council contained the main objections of the medical profession to the Bill. These points were also put forward by two other important medical bodies in their criticisms of the Bill—namely, the General Medical Council and the British Medical Association. The reply from Mr. Lloyd George was very unsatisfactory and misleading, for Mr. Lloyd George claimed that in the most important respects his own proposals were in accord with those made in the letter of the Council. In every point this was not correct. In the letter of the Council it had been stated that the administration of the medical service must not be placed in the hands of the Friendly Societies, yet the administration had really been put into the hands of the Friendly Societies, for in the Insurance Committees they had the controlling power. Further, in their letter the Council said that persons with incomes over £100 a year should not be permitted to receive medical benefit under the scheme, yet the Bill provided that those with incomes up to £160 must, and that those with incomes over this might, insure for medical benefits. The fifth resolution asked that no attempt should be made to force upon medical men a service which was not sufficiently well paid, and yet Mr. Lloyd George had replied that this was wrangling about fees in a sick-room. These points were enough to show how unsatisfactory was the official reply. The Chancellor of the Exchequer must have thought that he was dealing with children or fools if he believed that such an answer would satisfy them. He often boasted that he was giving 9*d*. for 4*d*., but it was by requiring the medical profession to do ninepennyworth of work for 4*d*. All of them should refuse to assist in this work until the objections put forward by the Council had been removed.

Mr. A. MAUDE seconded the motion, and said that the medical profession had been thrown back into the hands of the Friendly Societies, for these societies were to have 48 per cent. of the seats on the Insurance Committees, while there were to be only two or three medical men in a committee of possibly 80 members.

Mr. F. W. COLLINGWOOD claimed that payment should be made for services rendered.

Mr. ARCHER asked the Council to use its influence to induce other bodies to take action against the Bill. Mr. Lloyd George was not to be trusted.

Mr. MILWARD pointed out that without the assistance of the medical profession the Bill could not be worked. They

[1] THE LANCET, Sept. 2nd, 1911, p. 697.

could decide whether they should perpetuate the slavery of the Friendly Societies.

Several other Members spoke and then the President put the motion to the vote; it was carried by 26 votes to 2.

Mr. H. ELLIOT-BLAKE then moved—

That this meeting of the Fellows and Members desires the Council to obtain an Act of Parliament to authorise the change of the present and obsolete graduate titles of the College to the current and usual ones of M.D. or M.B., B.S.; and of F.S. and F.M. for the respective Fellowships. And for those purposes to seek corresponding power to regulate their university courses within the schools of the University of London or elsewhere.

He believed that the University Commission would come to nothing, and that the only hope for the future was for the Council to apply for an Act of Parliament to remove the present anomaly.

Mr. COLLINGWOOD seconded, and pointed out that if London had as many universities for its population as Scotland, it would have seven or eight.

Dr. LAWRENCE claimed that in this matter at least the Council had been trying to do its best for its Members, but it had failed.

The motion when put to the meeting was lost.

The third motion was moved by Mr. JOSEPH SMITH:—

That this twenty-seventh annual meeting of Fellows and Members again affirms the desirability of admitting Members to direct representation on the Council, which, as now constituted, does not represent the whole corporation; and that it does so in order that the constitution of the Council of the Royal College of Surgeons of England shall be in keeping with modern ideas of true representation.

He claimed that this was the twenty-seventh time that a resolution to the same effect had been moved at these meetings, and that it would not be possible for the Council much longer to ignore the resolutions of the Members. The matter had been so often before them that everyone was well acquainted with it, so that there was no need for him to say much.

Mr. COLLINGWOOD seconded, and several other Members spoke, and when the motion was put to the meeting it was carried without a dissentient vote.

The last motion was proposed by Dr. Lawrence:—

That this meeting of Fellows and Members requests the Council to include in their next annual report a balance-sheet showing fully and without reserve the assets and liabilities of the College on Midsummer Day, 1912.

He said that many Members felt a very natural anxiety to know how the money of the College was spent, and he held that it was very desirable to have a balance-sheet of the year's finances. The present accounts were too indefinite and amounted only to a profit and loss account.

Mr. J. BRINDLEY JAMES seconded.

The PRESIDENT said that of course he could not commit the Council, but the matter would receive consideration.

A vote of thanks to the President closed the proceedings.

MEDICINE IN THE ENCYCLOPÆDIA BRITANNICA.

IX.[1]—VACCINATION.

THE article on vaccination is one of great importance, and, as was to be expected of its author, Dr. S. Monckton Copeman, the subject is well and concisely handled. A brief account is first given of the way in which Jenner established on a scientific basis the fact, hitherto merely a piece of agricultural folk-lore, that cow-pox in a human being actually exercises a protective influence against small-pox. The relationship of cow-pox and small-pox is next reviewed. As evidence of a definite relationship between them it is pointed out that whereas, prior to the introduction of vaccination, epidemics of these disorders frequently arose concurrently, the so-called "natural" cow-pox has now in great measure disappeared. It is further suggested that an outbreak of small-pox may be turned to account for raising, by appropriate experimental methods, a fresh stock of vaccine lymph. It can be definitely stated, the author asserts, that small-pox lymph, especially if obtained from the primary vesicle of a case of the inoculated form of the disease, can be so altered in character by passage through the system of the calf as to become deprived of its power of causing a generalised eruption, while inducing at the site of inoculation a vesicle indistinguishable from a typical vaccine vesicle; and more important still, that when transferred again to man, it has by such treatment completely lost its infectious character. The generally admitted doctrine is therefore stated, "that cow-pox, or rather that artificially inoculated form of the disease which we term *vaccinia*, is nothing more nor less than *variola* modified by transmission through the bovine animal."

A very brief review of the constitution, work, and report, including its findings, of the Royal Commission on Vaccination is next given. In this connexion, we think, a little further account of the essential facts whereby medical science has proved the efficacy of vaccination might with advantage have been included. The public think too often that they can arrive at sound conclusions by the mere method of common sense in matters of which the solution may readily turn upon data with the very existence of which they are wholly unacquainted. It is desirable, therefore, that some idea of the data should be afforded them in such an authoritative publication as the "Encyclopædia Britannica."

The various objections that have been urged against the practice of vaccination fall naturally into two groups: (1) a denial of its efficacy; and (2) an assertion of its dangers. The latter of these, indeed, is given a paragraph to itself, but a categorical summary of the main observations whereby the proof of the protective efficacy of vaccination against small-pox has been established is omitted. Such observations are: (1) Cases of direct inoculation, or the so-called "variolous" test, consisting in the inoculation of efficiently vaccinated persons with variolous matter with negative results; (2) a comparison, embracing sufficiently long periods, of the prevalence and mortality of small-pox, respectively before and after the introduction of vaccination; (3) a comparison of the liability of the general public to small-pox with that of particular groups of efficiently vaccinated persons whose duties necessarily bring them into frequent and intimate exposure to infection—e.g., medical men, nurses, and hospital attendants, more especially those connected with small-pox hospitals; (4) the experience of the modifying effect of vaccination during epidemics, in which the complete stamping out of small-pox in Porto Rico and the Philippines—where it was heretofore endemic—under the enforcement of vaccination, offers perhaps the most striking demonstration yet afforded; and (5) a comparison of the mortality from small-pox in large vaccinated and non-vaccinated communities, of which a conspicuous example is to be found in Prussia since 1874, when vaccination and revaccination became compulsory, and in Austria, which still remains without compulsory vaccination, although since 1891 the Government has done all in its power to encourage the practice. Of the points established by these five observations the first, second, and third are briefly referred to in different parts of the article, but the fourth and fifth are unnoticed.

The necessity of "efficient" vaccination is properly insisted on, and its essentials are well stated as follows: "The clinical and bacteriological purity of the lymph employed for vaccination; the skilful performance of the operation itself; the making an adequate number of insertions of lymph over a sufficient area; the observance of precautions needful for insuring strict asepsis, both at the time of vaccination and subsequently until the vaccination wounds are soundly healed." It is of special importance in the comparatively small number of cases in which small-pox has occurred in vaccinated persons to establish the degree of efficiency of the reputed vaccination in the particular case. Glycerinated lymph, as now almost universally employed in Great Britain, is recommended, but a caution is given to be on the look out for its gradual weakening, such as is likely to occur from at present imperfectly understood conditions. On this point the author says: "Possibly the condition of the calves from which the lymph is obtained, especially as regards their general health and the suppleness or the reverse of their skins, or exposure of the lymph to the action of light or to a high temperature, are of special importance."

As regards the performance of the operation, the standard laid down by the Local Government Board, the production, namely, of a total area of vaccination of not less than half a

[1] Articles I., II., III., IV., V., VI., VII., and VIII. were published in THE LANCET of Feb. 25th (p. 530), March 4th (p. 609), 11th (p. 692), and 25th (p. 828), April 1st (p. 897) and 15th (p. 1026), Oct. 7th (p. 1035), and Nov. 11th (p. 1355), 1911, respectively.

square inch, divided among four separate vesicles or groups of vesicles not less than half an inch from one another, is urged for adoption by the private practitioner. Concerning attempted revaccination, in case of apparent failure it is held to be advisable, as in the case of a primary vaccination, to make further attempts with a lymph of known potency before concluding that the individual is really insusceptible.

In the section on alleged ill-effects it is shown that the danger of transmission of syphilis, which may have occurred with careless vaccinators in the days of arm-to-arm vaccination, may in future be disregarded, for the calf, from which animal all lymph is now obtained, is not capable of contracting syphilis, and therefore cannot contaminate its lymph therewith. Leprosy, like syphilis, is not communicable to the calf. The use of glycerine destroys by long exposure to it any tubercle bacilli, supposing such by any chance to be present in the lymph when collected. Skin eruptions are common in infancy, and they must be expected in about the same proportion of cases as under other conditions; and, finally, the author holds that no causative relation has been proved ever to have existed in the few cases in which eczema and impetigo have followed on vaccination.

The article concludes with an unsigned contribution describing the status of compulsory vaccination in the various countries and the course of legislation thereon in England, special stress being laid on the home vaccination of infants as now practised. This practice was a practical impossibility in the days of arm-to-arm vaccination. The "conscience clause" is discussed, and the conclusion is arrived at that it has not justified the gloomy forebodings expressed at the time of its insertion into the Act. On the contrary, it is stated that "its operation has appeared to tend to the more harmonious working of the Act."

MEDICINE AND THE LAW.

Medical Examinations under the Workmen's Compensation Act.

As medical men are well aware, the Workmen's Compensation Act, 1906, provides that "where a workman has given notice of an accident he shall, if so required by the employer, submit himself for examination by a duly qualified medical practitioner provided and paid for by the employer, and if he refuses to submit to such examination, or in any way obstructs the same, his right to compensation and to take or prosecute any proceeding under this Act in relation to compensation shall be suspended until such examination has taken place." Under this provision for enabling employers to ascertain for themselves the condition at a given time of the workman to whom they are paying, or are likely to have to pay, compensation, disputes have frequently arisen through the contention of workmen that they are not always fairly treated by the medical men representing the employers. The necessity for the detection of malingering requires the exercise of methods on the part of the medical man which the workman whose good faith is absolute may regard with excusable, if unjustifiable, apprehension, and which the malingerer, no doubt, resents as a very undesirable check upon his deceit. The medical man insists that he must make the examination alone; the workman, or his solicitor prompting him, demands the presence of a third party. An important decision of the House of Lords now seems to settle finally the law with regard to this matter upon lines already laid down in previous cases to which reference may first be made.

In THE LANCET of Sept. 17th, 1910, p. 899, comment was made in a leading article upon a case heard in the county court in which a workman was held to have refused to submit himself to examination by Dr. R. J. Collie unless the examination took place at his solicitor's office and in the presence of a member of the firm. His honour Judge Woodfall decided that this constituted a refusal to submit to examination in accordance with the Act. In THE LANCET of March 25th, 1911, p. 830, two similar cases which reached the Court of Appeal were described, in both of which Dr. Collie's name was again mentioned. In the one the workman had been required to submit to examination either at Dr. Collie's house in Porchester-terrace, W., or at his home in Holloway, and he had refused to be examined except at his solicitor's office and in the presence of a member of the firm. His honour Judge Bray, like his colleague Judge Woodfall, decided that this constituted a refusal, and the Court of Appeal confirmed his view, holding that the Workmen's Compensation Act gave no right to impose such conditions as those mentioned. In the second case the Court of Appeal had to decide as to a slightly different condition imposed by or on behalf of a workman—namely, that he should be examined either at the solicitor's office or at the surgery of the medical man who had attended him. In this instance his honour, the late Judge Bacon, was of the opinion upon the facts that there had not been a refusal to submit to examination, and the Court of Appeal upheld his decision, putting the point to be decided thus, "Was the refusal to go to the employers' doctor's surgery so unreasonable as to amount to a refusal to submit to examination or to obstruction?" and replying to this question in the negative. It was pointed out in comment upon this in THE LANCET of March 25th that the question of reasonableness was one of fact for the county court judge, who should take into consideration the material facts of the case before him.

The judgment of the House of Lords mentioned above had reference to yet another condition, and was delivered in a Scottish case upon appeal from a decision of the Court of Session upholding that of the sheriff substitute. The condition sought to be imposed by the working man was that his own medical attendant should be present at the examination made on behalf of the employers—that is to say, the House of Lords was asked to affirm, overruling the Court of Session, that there was "an abstract unconditional right in the workman to have his medical attendant present." This their lordships declined to do. They held that there was no such absolute and unconditional right, but that the question was one of fact, as to whether the condition sought to be imposed was reasonable, the burden of proof of reasonableness lying upon the workman. At the same time, the judgments of the Lord Chancellor and of Lord Atkinson, with whom Lord Gorell concurred, indicated that in their opinion the condition, or request, that the workman's medical attendant should be present might be a reasonable one, and Lord Shaw, who dissented from their judgment, had no doubt that the condition was in all cases reasonable. In his view it was the workman's right to have his medical adviser present, and he went so far as to say, according to the report of the case in the *Times*, that "he was sure that 95 per cent. of the medical practitioners in Scotland would prefer to have the assistance of a doctor on the other side." The word "assistance" needs explanation. As we understand the proposal, it is that the second medical man should be present, but should merely observe the proceedings, taking no part in them—at any rate, not unless invited to do so. To this there might well be no objection in many instances, and so much we have said. But the suggestion has been made that if the right to demand the presence of a second medical man were to be conceded, he should be the medical referee and not the workman's medical attendant. This is not likely to be a usual procedure. However, in conceivable cases the presence of the workman's medical adviser might be extremely objectionable to the employers' medical adviser; it might tend to lessen the efficacy of his examination in ascertaining the truth, and in such circumstances the demand would be "unreasonable." The question of "reasonableness" must govern the situation, and it is now settled law that the workman has no "abstract unconditional right" to demand that his own medical man should be present.

Exhibition Noises and Neighbouring Residents.

Mr. H. O. Becker, an artist living in the immediate neighbourhood of the Exhibition at Earl's Court, claimed an injunction and damages recently against the company carrying on business as Earl's Court Exhibition, Limited, in consequence of the annoyance caused to himself and his household by the noise of certain "side-shows" conducted in the Exhibition grounds. The action was heard by Mr. Justice Eve in the Chancery Division, and a large number of witnesses were called, including the plaintiff and his wife, Mr. Alfred Drury, A.R.A., Mr. Haldane Macfall, Mr. Herman Herkomer, and other artists and friends of the plaintiff, who testified to the impossibility of work or rest in the plaintiff's house while certain amusements were in progress in the Exhibition. Those particularly complained of were a railway of the familiar type actuated

by gravity and known as the Dragon's Gorge, and another amusement, consisting of moving platforms, and apparently much enjoyed by screaming and laughing pleasure-seekers, and a merry-go-round. The plaintiff complained that he was prevented from performing his professional work, and Mrs. Becker, in addition to other evidence, stated that her little daughter was unable to obtain sleep, and, in spite of the hot weather, had to have her bedroom windows closed at night in the attempt to keep out the noise. Mr. Justice Eve held that upon the evidence there had been such a use of the defendant's property as to cause sensible and material detraction from the comfort and enjoyment of the plaintiff's residence. In granting an injunction, he expressed the hope that it would not lessen the enjoyment which every sane and sensible human being ought to be glad to see his fellow-creatures partake of. The effect of it, however, would be to qualify that enjoyment and the mechanism of its production so that they would not inflict undue pain and suffering upon those living near. As no pecuniary loss had been proved by the plaintiff his lordship thought the justice of the case would be met by £25 as damages, the defendants paying the costs. The plaintiff is to be congratulated upon a result which must not only be satisfactory to himself but of which the benefit will presumably be shared by many of his neighbours. The judgment given may also tend to protect dwellers in other parts of London from disturbance in the enjoyment of their homes in peace and health, and may serve as a warning to amusement providers who, however much pleasure they may produce for a section of the public, have as their own motive not philanthropy but the desire to make money.

CENTRAL MIDWIVES BOARD.

A SPECIAL meeting of the Central Midwives Board was held on Nov. 14th at Caxton House, Westminster, with Sir FRANCIS H. CHAMPNEYS in the chair.

The Board considered the following charges amongst others against the midwives whose names are given below, and ordered such names to be struck off the Roll. Jane Blatherwick, that at the assizes held at Liverpool on July 1st, 1911, she was convicted of performing an illegal operation with intent to procure abortion, and was thereupon sentenced to seven years' penal servitude. Priscilla Briscoe, that when attending her patients she did not wear a clean dress of washable material that could be boiled, as required by Rule E, 1; that she did not take with her to a confinement the appliances or antiseptics required by Rule E, 2; and that she did not keep her register of cases as required by Rule E, 23. Mary Ann Cornfield, that being in attendance as a midwife at a confinement she was guilty of negligence in that, the patient's perineum being seriously ruptured, she did not explain that the case was one in which the attendance of a registered medical practitioner was required; nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E, 20 (3). Mary Ann Jackson, that being in attendance as a midwife at a confinement, the child suffering from inflammation of the eyes from birth, she did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner as required by Rule E, 19 (5) of the rules then in force. Charlotte Plenty, that she was uncleanly in her person and appliances; that she did not possess the appliances and antiseptics required by Rule E, 2; and that she did not take the temperature of her patients, being unable to use a clinical thermometer. Annie Marian Sadler, alias Palmer, that at the Central Criminal Court on July 5th, 1911, she was convicted on her confession of performing an illegal operation with intent to procure abortion, and was thereupon sentenced to five years' penal servitude. Elizabeth Ellen Watkins, that having been suspended from practice by the executive officer of the local supervising authority for a week from Tuesday, July 4th, 1911, on the ground of having attended a case of puerperal fever, she nevertheless attended as a midwife at a confinement and delivered the patient of a child on Friday, July 7th, 1911, without having undergone disinfection as required by Rule E, 5. Elizabeth Webb, that, being in attendance as a midwife at a confinement, the child suffering from inflammation of the eyes on the third day, she did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E, 20 (5).

The following midwives were censured after charges against them had been considered: Sarah Coulson and Caroline Fanny Wyatt. Annie Jane Maud Webb was cautioned after charges against her had been considered.

An adjourned special meeting of the Central Midwives Board was held on Nov. 16th at Caxton House, Westminster, with Sir FRANCIS H. CHAMPNEYS in the chair.

The following midwives were struck off the Roll, after the following charges against them had been considered:—Emily Flitton, that being in attendance as a midwife at a confinement, the child suffering from inflammation of the eyes on May 13th, she did not until May 16th explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E, 19 (5) of the rules then in force. Emma Holmes, that being in attendance as a midwife at a confinement, the patient suffering from hæmorrhage after the delivery, she did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner as required by Rule E, 19 (4) of the rules then in force. Alice Matthews, that she did not take with her to a confinement the appliances and antiseptics required by Rule E, 2; that she did not employ the antiseptic precautions required by Rules E, 3 and 7; and that she did not take the temperature of her patients, being unable to use a clinical thermometer. Rebecca Robinson, that being in attendance as a midwife at a confinement, a registered medical practitioner having been sent for, on her advice, she did not notify the fact to the local supervising authority as required by Rules E, 20 and 21 of the rules then in force; she did not enter the case in her register, as required by Rule E, 22 of the rules then in force. Emily Sturt, that being in attendance as a midwife at a confinement, she did not take with her the appliances and antiseptics required by Rule E, 2; she did not take the patient's temperature at any time. Mary Taylor, that being in attendance as a midwife at a confinement she neglected to attend to the comfort of the patient at the confinement and during the lying-in; the child having died before the attendance of a registered medical practitioner she did not notify the fact to the local supervising authority as required by Rule E, 20 of the rules then in force. Sarah May Walkling, that being in attendance as a midwife at a confinement, the case being one of twins, and the first presentation being abnormal, she did not explain that the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E, 19 (3) of the rules then in force. Ellen Florence Ward, that she was uncleanly in her person and clothing; that her house was uncleanly and insanitary; and that when attending a confinement she did not wear a dress of washable material, as required by Rule E, 1. Emma Willingham, that she was uncleanly and did not wear a dress of washable material; that she did not possess the appliances or adopt the antiseptic precautions required by the rules, and that she did not keep her register of cases as required.

The following midwives were censured after charges against them had been considered:—Harriet Sarah Eckersall and Annie Maud Hodder.

ASYLUM REPORTS.

Mental Hospital of the City of Cardiff (Report for the Year 1910).—The average daily number resident during the year in this hospital was 682. There were admitted 208 patients, of whom 121 were males and 87 females. 197 were direct admissions. Of those admitted, 41 suffered from delusional insanity, 48 from various degrees of melancholia, 54 from dementia, 28 from various degrees of mania, 25 from paralytic dementia, 8 from idiocy and imbecility, and 1 from moral insanity, while 3 persons were not insane. In 81 cases, or 39 per cent. of the admissions, a history of heredity of some kind was elicited. It is to be noted that 67 persons were admitted in a bad state of physical health, 76 in moderate health, and 62 in good health. The recoveries numbered 92. Calculated upon the number admitted, excluding transfers, this gives a recovery-rate of 46·7 per cent. Ten patients left relieved, and these figures taken altogether give a percentage of 51·7 discharged recovered and relieved. Of those who left recovered, nearly 37 per cent. were in residence for not more than four months. The deaths numbered 61, or 11·9 and 5·8 per cent. respectively of the average number of males and females daily resident. Necropsies were held in 56 of the 61 deaths. General paralysis was the cause of death in nearly 30 per cent. Dr. E. Goodall reports that he and Dr. H. A. Schölberg had been engaged upon an investigation into the Wassermann reaction in cases of paralytic dementia and other forms of insanity. The results have since appeared in the *Journal of Mental Science* for April, 1911. Dr. Goodall points out that hitherto the field of morbid histology has been worked in, almost to the exclusion of other fields, but that as the boundaries of research have now been extended far beyond this domain it becomes necessary that specially qualified workers in pathology, chemistry, and physiology should be employed. In recognition of this a research chemist and pathologist have recently been appointed on the staff of the hospital, and it is hoped that ere long an appointment in physiology will also be made.

Asylum for the Counties of Salop and Montgomery and for the Borough of Wenlock (Report for the Year 1910).—At this asylum the average daily number on the registers was 775. The admissions numbered 203, and of these 45 were re-admissions and 25 were transfers. The discharges amounted to 99, and of these 78 were discharged recovered. The proportions per cent. of recoveries to admissions were 44 for males and 36 for females. Of those recovered, 74 per cent. had been in residence for less than 12 months. The deaths numbered 109, being a percentage on the average number resident of 14·53. Of the deaths, 18·2 per cent. were caused by tubercular disease and 4·6 per cent. by general paralysis. Dr. D. F. Rambaut reports that on March 31st of this year the partnership in the asylum between the county of Salop and borough of Wenlock on the one hand, and the county of Montgomery on the other, was dissolved. At the end of March and the beginning of April all the Montgomeryshire patients were transferred to the Cardiff, Cotford, and Powick asylums, except 14 patients whom it was dangerous to move.

Hereford County and City Lunatic Asylum at Burghill, near Hereford (Report for the Year 1910).—The daily average number resident at this asylum was 504. The admissions numbered 82, of whom 45 were males and 37 females. Of these, 21·9 per cent. were cases of mania, 12·2 per cent. cases of melancholia, 10·9 per cent. cases of delusional insanity, 12·2 per cent. cases of dementia, and 25·6 per cent. cases of mental defect (imbeciles and idiots). It is unsatisfactory to notice that the admissions represent a high percentage of dements and mental defectives, a group constituting a class in whom mental recovery is practically hopeless. Mr. C. S. Morrison, the medical superintendent, regards the percentage of mental defectives as foreshadowing in a measure the danger that underlies agricultural depression in the heart of the community. In the direct admissions insane heredity or some degree of congenital mental deficiency was ascertained to be present in 50 per cent. of the total cases. The standard of bodily health in the majority was very poor. The discharges numbered 42, of whom 13 males and 14 females had recovered, giving a percentage of recoveries calculated on the number of admissions of 34·2. The deaths numbered 33, giving a percentage calculated on the daily average number resident of 6·5, being 9·6 for males and 4·2 for females. The average age at death was 57. The number of post-mortem examinations was 23, being 69·7 per cent. of the total number of deaths.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 77 of the largest English towns, having an estimated population of 16,157,797 persons in the middle of this year, 7784 births and 4319 deaths were registered during the week ending Nov. 18th. The annual rate of mortality in these towns, which had been 13·3, 13·5, and 13·1 in the three preceding weeks, rose to 13·9 per 1000 in the week under notice. During the first seven weeks of the current quarter the mean annual rate of mortality in these towns averaged 14·0, or 0·2 per 1000 above the rate recorded in London during the same period. The death-rates in the 77 towns last week ranged from 6·4 in King's Norton, 6·6 in Wallasey, 7·6 in Burton-on-Trent, and 7·7 in Grimsby, to 19·3 in Middlesbrough, 19·6 in Stockport, 20·0 in Stockton-on-Tees, and 21·4 in Sunderland. The 4319 deaths from all causes in the 77 towns were 263 in excess of the number in the previous week, and included 267 which were referred to the principal epidemic diseases, against numbers decreasing from 2900 to 279 in the 12 preceding weeks. Of these 267 deaths, 76 resulted from infantile diarrhœa, 64 from diphtheria, 51 from measles, 31 from whooping-cough, 24 from enteric fever, and 21 from scarlet fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases last week was equal to 0·9 per 1000, against 1·0 and 0·9 in the two preceding weeks. The deaths of infants under two years of age attributed to diarrhœa, which had steadily decreased from 2714 to 113 in the 12 preceding weeks, further declined to 76 last week, and caused the highest death-rates of 1·1 in Oldham and 2·1 in Aston Manor. The deaths referred to diphtheria, which had been 46, 56, and 55 in the three preceding weeks, rose to 64 last week; 21 deaths occurred in London and its suburban districts, 4 in Stoke-on-Trent, and 3 each in Bolton, Bradford, Leeds, and Swansea. The fatal cases of measles, which had been 48, 36, and 37 in the three previous weeks, further rose to 51 last week, and included 13 in London and its suburban districts, 9 in Salford, 6 in Manchester, and 3 in Oldham. The deaths attributed to whooping-cough, which had been 30, 16, and 24 in the three preceding weeks, rose to 31 last week; 7 deaths were registered in London, 3 in St. Helens, and 3 in Sunderland. The deaths referred to enteric fever, which had been 28, 35, and 24 in the three preceding weeks, were again 24 last week, and included 4 in Hull, 3 in Birmingham, and 3 in Sheffield. The fatal cases of scarlet fever numbered 21, against 30 and 26 in the two previous weeks, and included 5 in London and 3 in Stoke-on-Trent. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily increased from 1327 to 2203 in the 11 preceding weeks, had further advanced to 2213 on Saturday last; 291 new cases of this disease were admitted to these hospitals during the week, against 297, 269, and 292 in the three previous weeks. These hospitals also contained on Saturday last 1282 cases of diphtheria, 175 of whooping-cough, 121 of enteric fever, and 84 of measles, but not one of small-pox. The 1128 deaths from all causes in London last week were 20 in excess of the number in the previous week, and included 224 which were referred to diseases of the respiratory system, against 210, 170, and 196 in the three preceding weeks. The deaths attributed to different forms of violence in the 77 towns, which had declined from 158 to 136 in the three preceding weeks, rose to 167 last week, and 371 inquest cases were registered. The causes of 37, or 0·9 per cent., of the deaths registered in the 77 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified last week in London and its 8 suburban districts, in Sheffield, Leeds,

Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, and in 44 other smaller towns. The 37 uncertified causes of death in the week under notice included 8 in Liverpool, 4 in Gateshead, and 3 each in Birmingham, Preston, and South Shields.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 770 births and 611 deaths were registered during the week ending Nov. 18th. The annual rate of mortality in these towns, which had declined from 16·7 to 16·3 in the three preceding weeks, rose to 18·6 per 1000 in the week under notice. During the first seven weeks of the current quarter the mean annual death-rate in these Scotch towns averaged 16·4 per 1000, and was 2·4 per 1000 above the mean rate during the same period in the 77 large English towns. The annual death-rates in the several Scotch towns last week ranged from 12·3 in Dundee and 12·9 in Leith to 20·8 in Greenock and 21·7 in Aberdeen. The 611 deaths from all causes were 78 in excess of the number in the previous week, and included 65 which were referred to the principal epidemic diseases, against 47 and 48 in the two preceding weeks; of these 65 deaths, 28 resulted from measles, 19 from diarrhœa, 8 from diphtheria, 4 from scarlet fever, 4 from whooping-cough, and 2 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 2·0 per 1000, and was 1·1 per 1000 above the mean rate from the same diseases in the 77 large English towns. The deaths referred to measles, which had been 12, 15, and 13 in the preceding weeks, rose last week to 28, of which 16 were recorded in Aberdeen and 9 in Glasgow. The deaths attributed to diarrhœal diseases, which had declined from 41 to 9 in the five preceding weeks, rose last week to 19, all of which related to children under two years of age; 11 deaths were registered in Glasgow, 4 in Edinburgh, and 3 in Dundee. The fatal cases of diphtheria, which had increased from 5 to 14 in the four preceding weeks, declined to 8 last week, and included 4 in Glasgow and 2 in Aberdeen. The deaths referred to scarlet fever, which had declined from 8 to 2 in the six preceding weeks, rose to 4 last week, and included 2 in Aberdeen. Of the 4 deaths attributed to whooping-cough, which were slightly above the average in recent weeks, 2 were recorded in Glasgow and 2 in Aberdeen. The 2 fatal cases of enteric fever were registered in Glasgow. The deaths referred to diseases of the respiratory system, which had been 111, 116, and 108 in the three preceding weeks, rose to 144 in the week under notice, and were 23 above the number in the corresponding week of last year. Of the 611 deaths from all causes in the Scotch towns last week, 162, or 27 per cent., were recorded in public institutions, and 44 were attributed to different forms of violence. The causes of 23, or 3·8 per cent., of the deaths in the eight towns last week were not certified or not specified; in the 77 large English towns the proportion of uncertified causes did not exceed 1·0 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 529 births and 419 deaths were registered during the week ending Nov. 18th. The annual rate of mortality in these towns, which had increased from 17·1 to 17·6 in the three preceding weeks, further rose to 19·0 per 1000 in the week under notice. During the first seven weeks of the current quarter the mean annual death-rate in these Irish towns averaged 18·3 per 1000; in the 77 large English towns the mean annual death-rate during the same period did not exceed 14·0 per 1000, while in the eight Scotch towns it was equal to 16·4. The annual death-rate last week was equal to 22·1 in Dublin (against 13·0 in London), 17·7 in Belfast, 25·9 in Cork, 16·6 in Londonderry, 9·5 in Limerick, and 13·3 in Waterford; while in the 16 smallest of these Irish towns the annual death-rate did not exceed 15·4 per 1000. The 419 deaths from all causes were 31 in excess of the number in the previous week, and included 47 which were referred to the principal epidemic diseases, against numbers decreasing from 134 to 33 in the nine preceding weeks; of these 47 deaths, 19 resulted from diarrhœal diseases, 12 from diphtheria, 8 from measles, 5 from whooping-cough, and 3 from scarlet fever, but not one from enteric fever or from small-pox. These 47 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·2 per 1000; in the 77 English towns the mean death-rate from these diseases last week did not exceed 0·9 per 1000, while in the eight Scotch towns it was equal to 2·0. The deaths attributed to diarrhœal diseases, which had steadily declined from 121 to 10 in the nine previous weeks, rose to 19 last week, and included 17 of infants under two years of age; 6 deaths were recorded in Belfast, 5 in Dublin, and 3 in Cork. The deaths referred to measles, which had increased from 1 to 9 in the five preceding weeks, numbered 8 last week, of which 5 occurred in Dublin and 2 in Cork. Of the 5 fatal cases of whooping-cough, which were slightly in excess of the average in recent weeks, 4 occurred in Dublin and 1 in Belfast. The 3 deaths assigned to scarlet fever were equal to the average number in the five preceding weeks, and comprised 2 in Dublin and 1 in Belfast. The deaths referred to diseases of the respiratory system, which had been 77 and 75 in the two preceding weeks, further fell to 73 last week. Of the 419 deaths from all causes in the Irish towns during the week under notice, 153, or 37 per cent., were recorded in public institutions, and 9 were attributed to different forms of violence. The causes of 13, or 3·1 per cent., of the deaths registered in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes last week did not exceed 0·9 per cent. in the 77 large English towns, but was equal to 3·8 per cent. in the eight Scotch towns.

VITAL STATISTICS OF LONDON DURING OCTOBER, 1911.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 8·5 per 1000 of the population, estimated at 4,522,628 persons in the middle of the year. In the three preceding months the rates were 5·1, 4·4, and 6·9 per 1000 respectively. The lowest rates last month were recorded in Chelsea, the City of Westminster, Hampstead, Holborn, and the City of London; and the highest rates in St. Marylebone, Hackney, Shoreditch, Deptford, Greenwich, and Woolwich. Scarlet fever showed a greatly increased prevalence compared with that recorded in any other recent month; among the several metropolitan boroughs this disease was proportionally most prevalent in St. Marylebone, Hackney, Shoreditch, Lambeth, Deptford, Greenwich, and Woolwich. The Metropolitan Asylums Hospitals contained 2152 scarlet fever patients at the end of last month, against 1400, 1324, and 1656 at the end of the three preceding months; the weekly admissions averaged 317, against 200, 159, and 261 in the three preceding months. Diphtheria also was considerably more prevalent than it had been in several preceding months; the greatest proportional prevalence of this disease was recorded last month in St. Pancras, Stoke Newington, Finsbury, Wandsworth, and Greenwich. There were 1143 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 839, 720, and 892 at the end of the three preceding months; the weekly admissions averaged 168 last month, against 120, 85, and 138 in the three preceding months. The cases of enteric fever notified during October showed a marked decrease from the abnormally high number in the previous month; among the several metropolitan boroughs this disease was proportionally most prevalent in Fulham, Hackney, Shoreditch, Stepney, Poplar, and Southwark. The number of enteric fever patients under treatment in the Metropolitan Asylums Hospitals, which had been 47, 56, and 155 at the end of the three preceding months, was 160 at the end of last month; the weekly admissions averaged 23, against 9, 10, and 39 in the three preceding months. The greatest proportional prevalence of erysipelas was recorded in Hackney, Finsbury, Shoreditch, Bethnal Green, Stepney, Bermondsey, Deptford and Greenwich. The 23 cases of puerperal fever notified during the month included 4 in Islington, 4 in Lambeth, 3 in

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING OCTOBER, 1911.

* Including membranous croup. † The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard. ‡ Deaths from "typhus fever" and "other continued fevers" are not now distinguished in the Registrar-General's weekly returns; these two columns are therefore omitted from the Table.

Bethnal Green, 3 in Lewisham, 2 in Chelsea, and 2 in the City of Westminster. The 5 cases of cerebro-spinal meningitis belonged respectively to Hammersmith, the City of Westminster, Islington, Poplar, and Southwark.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex- and age-constitution of the population of the several boroughs. During the four weeks ending Oct. 28th the deaths of 5004 London residents were registered, equal to an annual rate of 15·1 per 1000, against 12·4, 18·9, and 16·8 per 1000 in the three preceding months. The death-rates last month ranged from 11·0 in Wandsworth, 11·5 in Lewisham, 12·1 in Kensington and in Hampstead, and 12·8 in Holborn, to 17·2 in Poplar, 19·2 in Southwark, 19·5 in Bermondsey, 20·6 in Finsbury, and 23·2 in Shoreditch. The 5004 deaths from all causes included 38 from measles, 13 from scarlet fever, 51 from diphtheria, 20 from whooping-cough, 25 from enteric fever, and 370 among children under two years of age from diarrhœa and enteritis. No death from any of these diseases was recorded last month in Holborn; among the other boroughs they caused the lowest death-rates in Chelsea, the City of Westminster, St. Marylebone, Hampstead, and the City of London, and the highest rates in Shoreditch, Poplar, Southwark, Bermondsey, Deptford, and Greenwich. The 38 deaths from measles were 13 fewer than the corrected average number in the corresponding period of the five preceding years; of these 38 deaths, 12 belonged to Deptford, 9 to Camberwell, 7 to Southwark, 3 to Bermondsey, and 2 each to Lambeth and Islington. The 13 fatal cases of scarlet fever were 31 below the corrected average number, and included 4 in St. Pancras and 2 in Islington. The 51 deaths from diphtheria were 6 in excess of the corrected average number; of these 51 deaths, 7 belonged to Islington and 4 each to Shoreditch, Stepney, Poplar, Lambeth, Lewisham, and Woolwich. The 20 fatal cases of whooping-cough were less than one-half the corrected average number in the corresponding period of the five preceding years; 3 of these deaths belonged to Poplar, 3 to Lambeth, 2 to St. Pancras, 2 to Hackney, and 2 to Finsbury. The 25 deaths referred to enteric fever were 6 below the corrected average, and included 4 in Poplar, 3 in Kensington, 3 in Islington, 3 in Hackney, 2 in Finsbury, 2 in Battersea, and 2 in Lewisham. The 370 deaths from diarrhœa and enteritis among children under two years of age showed a decline of 999 from the number recorded in the previous four weeks; the greatest proportional mortality from this cause last month occurred in Paddington, Shoreditch, Bermondsey, Deptford, and Greenwich. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases (excluding diarrhœa) was 69 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned Staff-Surgeons have been promoted to the rank of Fleet-Surgeon in His Majesty's Fleet: Charles Henry James Robinson, Harold Huskinson, Ernest Sydney Tuck, Murray Parry Jones, Arthur William Bligh Livesay, Herbert Hope Gill, William Reynolds Trythall, John Charles Rowan, Richard Adolphus Ross, and Michael Joseph Smith (dated Nov. 12th, 1911).

The following appointments have been notified:—Fleet-Surgeons: R. A. Fitch to the *Neptune*, for service on staff of Commander-in-Chief, Home Fleet; E. Hodnet de Courtmacsherry to the *Hercules*, for service on staff of Vice-Admiral Commanding 2nd Division, Home Fleet; J. H. Stenhouse to the *King Edward VII.*, for service on staff of Vice-Admiral Commanding 3rd and 4th Divisions, Home Fleet; J. Andrews to the *Exmouth*, for service on staff of Commander-in-Chief, Mediterranean; P. B. Handyside to the *Minotaur*, for service on staff of Commander-in-Chief, China; V. G. Thorpe to the *Powerful*, for service on staff of Commander-in-Chief, Australia; G. A. Dreaper to the *Hermes*, for service on staff of Commander-in-Chief, Cape; E. Sutton to the *Highflyer*, for service on staff of Commander-in-Chief, East Indies; E. B. Pickthorn to the *Prince of Wales*, for service on staff of Vice-Admiral Commanding Atlantic Fleet; C. S. Woodwright to the *Leviathan*, for service on staff of Rear-Admiral Commanding Fourth Cruiser Squadron; R. Hill, M.V.O., to the *Medina*, for service on staff of Rear-Admiral Commanding Detached Squadron; W. R. Trythall to the *Roxburgh;* P. W. Bassett-Smith, C.B., to the *President*, additional, for duty as Professor of Clinical Pathology in the Naval Medical School, Greenwich; A. Gaskell to the *President*, additional, for three months' course of special study in metropolitan hospitals and for duty as Professor of Hygiene and in charge of studies at Naval Medical School, Greenwich; F. H. A. Clayton to the *President*, additional, for three months' course of special study in metropolitan hospitals, to the *Victory*, additional, for Haslar Hospital, and to Haslar Hospital as Instructor of Acting Surgeons and in charge of Junior Medical Section. Staff-Surgeons: W. L. Martin to the Medical Department and R. W. Stanistreet to the *Empress of India*. Surgeon: A. Fairley to the *Roxburgh*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel John C. Haslett, Half-pay List, is placed on retired pay (dated Nov. 16th, 1911).

The undermentioned Majors to be Lieutenant-Colonels (dated Nov. 2nd, 1911):—John W. Bullen, vice C. A. Young, supernumerary; and Benjamin J. Inniss, vice J. Will, supernumerary.

Major Gerald B. Carter retires receiving a gratuity (dated Nov. 8th, 1911).

The undermentioned Captains to be Majors (dated Nov. 17th, 1911):—Edward W. Siberry and Basil F. Wingate.

Colonel Sir David Bruce, F.R.S., expert on tropical diseases to the Army Medical Advisory Board, has left the London District for duty in Nyassaland under the Colonial Office. Colonel L. E. Anderson has taken up duty as Principal Medical Officer of the Bareilly, Garhwal, and Dehra Dun Brigades with headquarters at Bareilly. Lieutenant-Colonel W. H. Starr, on transfer from India, has been posted to the Eastern Command. Lieutenant-Colonel W. C. Beevor, C.M.G., lately commanding the station hospital at Bangalore, has on arrival home been ordered to join the Irish Command for appointment to medical charge of the Military Hospital at Fermoy, vice Major C. J. Healy. Lieutenant-Colonel J. M. F. Shine, from Fyzabad, has been placed in medical charge of the troopship *Plassy*, which left Bombay for Southampton on Nov. 9th. Lieutenant-Colonel H. W. Austin has been placed in medical charge at Fort Stamford. Lieutenant-Colonel W. W. Pike, D.S.O., has arrived home on leave of absence from Egypt. Lieutenant-Colonel W. Turner, in charge of the Military Hospital at York and commanding No. 8 Company, R.A.M.C., has been transferred to Aldershot, to take charge of the Connaught Hospital. Lieutenant-Colonel J. Fallon, lately in medical charge at Preston, has embarked for a tour of foreign service with the Northern Army in India. Lieutenant-Colonel N. C. Ferguson, C.M.G., has been transferred from Queen Alexandra's Military Hospital, Grosvenor-road, to the Northern Command to take over charge of the Military Hospital at York. Major B. J. Inniss, in charge of the Military Hospital at Gravesend, has, on promotion, been transferred to Ireland to take charge of the Military Hospital at Belfast. Major L. P. More has taken up duty at Portsmouth in charge of the reception hospital. Major T. H. J. C. Goodwin, D.S.O., from Aden, has been transferred to the home establishment. Major F. J. C. Heffernan has embarked for India for a tour of foreign service. Major J. P. Silver, company officer at Edinburgh, has been granted leave of absence to Dec. 16th. Major W. Hallaran has been appointed to command at the station hospital at Chakrata, in succession to Lieutenant-Colonel S. Westcott, C.M.G., tour-expired. Major G. M. Goldsmith has been transferred from Maymyo to the Eighth (Lucknow) Division. Major W. T. Mould, company officer at Dover, has been detailed by the War Office for a tour of service in India, embarking at an early date. Major A. M. MacLaughlin, specialist sanitary officer in the Scottish Command, has been granted leave of absence until Dec. 4th. Major L. Wood, adjutant of the Royal Army Medical Corps School of Instruction at Manchester, has been detailed for transfer to Burma. Major C. E. P. Fowler, specialist sanitary officer at Gibraltar, has arrived home on leave of absence. Major S. H. Withers, commanding the station

hospital at Gharial, has been selected for appointment to command the Station Hospital at Dagshai for a period of two years with effect from March next. Major D. Harvey has left the London District for duty in Nyassaland under the Colonial Office. Captain P. J. Hanafin has taken up duty as Specialist in Ophthalmology in the Dublin District. Captain C. W. Holden has been transferred from Tientsin to Shan-Hai-Kuan. Captain A. C H. Gray has taken up duty as Clinical Pathologist at the Royal Infirmary, Dublin. Captain H W. Farebrother has received one month's extension of his leave of absence on the recommendation of a medical board. Captain A. Dawson has been transferred from the Ninth (Secunderabad) Division to the Aden Brigade and placed in charge of the Brigade Bacteriological Laboratory in succession to Captain E. W. Powell, returning home tour-expired. Captain J. S. Bostock has embarked for a tour of service in India for duty with the Northern Army. Captain P. G. Patch has taken up duty in the northern command as Specialist in Otology, Rhinology, and Laryngology. Captain A. McMunn, from Portobello Military Hospital, Dublin, has joined at Hong-Kong for a tour of service. Captain G. E Ferguson, on return home from Cyprus, has been appointed to the Southern Command. Captain A. R. C. Parsons, specialist in advanced operative surgery at Edinburgh, has been granted leave of absence from Dec. 18th to Jan. 17th. Captain C. A. Morris, C.V.O., attached to the 16th Battalion London Regiment (Queen's Westminster Rifles), has been selected for a course of instruction at the Queen Alexandra Military Hospital, Millbank, from the 6th inst. Captain H. H. A. Emerson has taken up duty at Clonmel. Captain W. MacD. MacDowall has been transferred from Aldershot to Ewshott. Lieutenant F. W. M. Cunningham, on the closing of Donard Camp, has been appointed for duty to the Curragh. Lieutenant R. M. Davies, from Landguard Fort, has taken up duty at Chatham. Lieutenant C. Robb, from the Curragh, has been selected for employment with the Public Health Department of the Government of Egypt. Lieutenant E. C. Stoney has been placed in charge of staff and families at Colchester, in succession to Lieutenant R. C. Priest.

INDIAN MEDICAL SERVICE.

Surgeon-General A. M. Crofts, C.I.E., has taken up duty as Principal Medical Officer of the Second (Rawalpindi) Division of the Northern Army. Lieutenant-Colonel W. R. Edwards, C.M.G., administrative medical officer of the North-West Frontier Province, has been granted one year's leave of absence home from India Lieutenant-Colonel M. A. Ker has been appointed to the Medical Charge of the 2nd Battalion 5th Gurkha Rifles, in succession to Lieutenant-Colonel C. E. L. Gilbert, transferred to the Medical Charge of the 26th Punjabis at Samana. Lieutenant-Colonel W. B. Lane, Inspector-General of Prisons in the Central Provinces, has been granted 18 months' leave of absence home from India. Lieutenant-Colonel L. F. Childe has been appointed Senior Medical Officer at the Parsi Hospital, Bombay, and will act as Principal of the Grant Medical College during the absence of Lieutenant-Colonel C. H. L. Meyer. Lieutenant-Colonel L. G. Fischer has been selected for appointment as a Civil Surgeon of the First Class in succession to Lieutenant-Colonel L. J. Pisani, retired. Major S. P. James, statistical officer with the Government of India, has been selected to proceed to the Panama Canal to report on investigations in connexion with yellow fever being carried out in that locality. Major E. C. Peck has relinquished charge of the duties of Superintendent of the Jullundur Jail. Major W. H. Kenrick, on special duty in the office of the Sanitary Commissioner of the Central Provinces, has been appointed to officiate as Sanitary Commissioner of the Central Provinces during the absence home on leave of Major T. G. M. Stokes, the permanent incumbent. On return from leave Major T. Stoddart has taken up duty as Civil Surgeon of the Ruby Mines District, relieving Captain H. S. Matson. Captain E. H. B. Stanley has been granted one year's leave of absence home from India Captain N. S. Wells, Civil Surgeon in the United Provinces, has been granted one month's leave on Medical Certificate. Captain W. S. McGillivray has been selected for appointment to the Substantive Medical Charge of the 41st Dogras.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Hubert Cox is confirmed in his rank.

TERRITORIAL FORCE.

Royal Army Medical Corps.

Captain John Marcus Hobson Conway, R.A.M.C., to be Adjutant of a School of Instruction (dated Nov. 1st, 1911).

1st Highland Field Ambulance, Royal Army Medical Corps: Lieutenant James Robertson to be Captain (dated Oct. 14th, 1911).

2nd Highland Field Ambulance, Royal Army Medical Corps: Lieutenant James F. Mackintosh to be Captain (dated Oct. 14th, 1911).

3rd Highland Field Ambulance, Royal Army Medical Corps: The undermentioned officers to be Captains (dated Oct. 1st, 1911): Lieutenant James M. Smith and Lieutenant John H. Hunter.

3rd Home Counties Field Ambulance, Royal Army Medical Corps: Lieutenant Thomas Francis Roche, from the List of Officers of the Royal Army Medical Corps attached to Units other than Medical Units, to be Lieutenant (dated Nov. 15th, 1911). Lieutenant Edwin Augustus Houchin, from the 2nd Home Counties Field Ambulance, Royal Army Medical Corps, to be Lieutenant (dated Nov. 15th, 1911).

2nd London (City of London) Field Ambulance, Royal Army Medical Corps: Lieutenant Francis R. Humphreys to be Captain (dated Oct. 1st, 1911).

2nd North Midland Field Ambulance, Royal Army Medical Corps: Lieutenant James R. Plant resigns his commission (dated Nov. 15th, 1911).

3rd North Midland Field Ambulance, Royal Army Medical Corps: Lieutenant Andrew E. Hodder to be Captain (dated March 24th, 1911).

1st West Riding Field Ambulance, Royal Army Medical Corps: Lieutenant James Ewing to be Captain (dated Oct. 1st, 1911).

1st Welsh Field Ambulance, Royal Army Medical Corps: Lieutenant John Buckner to be Captain (dated Oct. 1st, 1911).

1st Scottish General Hospital, Royal Army Medical Corps: Lieutenant-Colonel James M. Booth resigns his commission and is granted permission to retain his rank and to wear the prescribed uniform (dated Nov. 15th, 1911).

Attached to Units other than Medical Units.—Captain David J. Penney to be Major (dated Sept. 20th, 1911). Lieutenant Winstan St. A. St. John to be Captain (dated Oct. 1st, 1911). Captain John B. Stevens to be Major (dated Oct. 4th, 1911). Lieutenant-Colonel William R. Sewell resigns his commission and is granted permission to retain his rank and to wear the prescribed uniform (dated Nov. 15th, 1911). Captain John S. Mackay resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated Nov. 15th, 1911).

For Attachment to Units other than Medical Units.—James Hogg Martin to be Lieutenant (dated Oct. 17th, 1911).

HEALTH OF THE ARMY IN 1910.

The Director-General's Annual Report on the Health of the Army for the Year 1910 (Vol. LII.) has just been published by His Majesty's Stationery Office, and is now on sale at the price of 1*s.* 9*d.* each copy. In his introductory letter to the Secretary of the War Office, Sir William Gubbins draws attention to the steady improvement in the health of the troops which has been in progress for the past 12 years or so, and which was well maintained during 1910. The ratios per 1000 of strength, for troops at home and abroad, of admissions, of deaths, of invalids sent home, and of soldiers constantly sick were in 1910 the lowest on record and showed a considerable decrease on the previous year. The ratio of invalids finally discharged was a trifle higher than in 1909, but was lower than any other previous ratio, while the average sick time (9·15 days) per man was 1·24 days less than in 1909. These figures are most satisfactory, and are naturally attributed by the Director-General to the increased attention which of late years has been paid to personal hygiene and general sanitation among our troops by those responsible for their health.

THE CORONATION DURBAR AT DELHI.

Colonel S. J. Rennie, commanding the Northern Regiment, United Provinces Horse, has been selected to command the Volunteer Cavalry at the Coronation Durbar to be held at Delhi. Colonel Rennie retired from the Royal Army Medical Corps and settled in practice at Mussooree some few years ago. He was shortly afterwards appointed to command the Dehra Dun Volunteer Cavalry.

Correspondence.

"Audi alteram partem."

THE NATIONAL INSURANCE BILL.

To the Editor of THE LANCET.

SIR,—I am one of those who believe that in principle contract payment is the best. All members of the profession engage in contract practice, more or less. The general practitioner engages to attend a confinement at a fixed sum to include after visits; the operating surgeon does the same for his work. All paid appointments are on the same basis. "Payment for work done," as the phrase goes, would not be secured by a fixed sum per visit (also a contract by the way). There is considerable difference in value between a first visit, when 30 or 40 minutes may be spent in examination, &c., and subsequent ones, when five minutes are often sufficient, and also between night and day, special and routine visits. If all these and other conditions are to be separately rated, half one's time will be spent in working out what is due. Adequate payment for a variety of services can only be arrived at by lumping them all together.

Sir Alfred Pearce Gould says: "The doctors would have to accept small cash fees, and to *insist on their payment at the time*." This to my mind is a fatal objection to the scheme. Consultants, perhaps, are not practically familiar with general practice amongst the poor. Imagine a man in a crowded cottage just having ordered certain things which the mother of the sick child says she cannot possibly afford; the doctor is to reply, "I am sorry for that; my fee, please," and take it, in sixpenny bits and coppers, with one eye on the child for whom some necessary cannot be bought. The fee would not always be paid, consequently bad debts and cash-books would continue as now.

Many writers offer as a test of contract practice its application to all classes, and mention as against it that the system was founded on charity. Surely the fact that any scheme is originally founded on one idea is not to bar its application for ever to any other if otherwise suitable? The only charitable element in club practice is the *amount* of the capital fee, and as to the universal application I personally think that it would be quite suitable for general practice. Again, the close association of work and payment is mentioned as sweetening both; on the contrary, I think the one objection to the practice of medicine is the daily valuation of one's services. It would be an ideal life with an assured sufficient income—no accounts to keep, no bills to send out, no bad debts, and no hints and suspicions of unnecessary zeal. The one valid objection is "unreasonable demands on the doctor and malingering." The suggested remedy for this is that the poor man shall pay for each visit, receiving an extra grant for the purpose; either this extra grant would exactly equal the doctor's bill or it would not; in the former case there is no stimulus; in the latter, if it is more, the patient retains money that ought to go to the profession, and if it is less the doctor won't get paid!

No scheme which provides that the patient pays the doctor's bill will meet the primary object of the Bill, which is to make certain provision for medical attendance on the poor at all times, for the simple reason that any doctor, and therefore all doctors, could refuse to attend any given individual who had a bad reputation with regard to paying. Some months ago, in a letter to the *Times*, I suggested that unreasonable demands could easily be got over by debiting the patient with a small charge for each visit. The doctor would merely have to initial a card at each visit and the necessary total would be deducted from the payments made to the patient. This would check unnecessary calls and secure that the patient pays somewhat according to the attention he requires.

It is said that if the sum paid to the profession under the scheme of "contract" is "adequate," it must equal the total sum that should be paid by the sick members of the insured community under the ordinary method of payment for work done. Quite so. Let that sum be properly ascertained, as it can be actuarially. Insurance companies do not fix their premium rates at the dictation of a Chancellor, neither should we. Mr. Lloyd George has consulted professional men to work out other money items, and he should be asked to utilise their services to work out this question also. The sum of money, therefore, required to remunerate the profession would be the same in either case, with *this* difference: "For work done" the practitioner would have to collect it himself, and would then probably always receive something less than 100 per cent. *Per capita* he would get 100 per cent. paid quarterly, and no unpleasantness about it.

A simple and satisfactory scheme would be: 1. A sum of 10*s.* (or other amount properly ascertained) for every individual who did not pay income tax. 2. A fine of 1*d.* per £1 of weekly income for each visit. 3. Free choice of doctor, half-yearly. 4. Consultations, midwifery, surgery, anæsthetics to be paid either extra or dealt with at an institution.

The income-tax limit is far simpler than one based on fluctuating earnings and, the *pay being adequate*, the exact line of admission is immaterial. Such a system would practically wipe out all bad debts and gratuitous work, and the profession would be able to accept everybody within the income limit, without further haggling over this and that, merely arranging amongst themselves for a fair distribution of "chronics" and other undesirables whom nobody wants but somebody must attend. I cannot understand how anyone can think it more dignified and honourable to accept small cash fees from labourers and domestics than to receive quarterly a cheque from the State. There is nothing undignified in receiving a cheque of 100 guineas from the donor's hand, but when it comes to accepting a silver coin from a domestic, who later in the day may receive it back again for helping on one's coat after dining out, the word dignity is out of place. I hope the profession will not be led away by such phrases as "the thraldom of contract practice" to reject a certain and easy method of payment for a vexatious and uncertain one, under a system which is every bit as much a contract as the other. The only thraldom I know of is to be overworked and underpaid.

The whole thing for us turns on one point only—£ *s. d.* The one and immediate thing the profession has to do is to insist that the *per capita* sum shall be ascertained by professional experts and not guessed at or based on charitable schemes of the past, and have the sum fixed for the whole country and named in the Bill. The constitution of the Health Committees will then be of no moment, and there will be no local disputes between those committees and the profession—a great danger as matters stand at present.

I am, Sir, yours faithfully,

PENROSE WILLIAMS, F.R.C.S. Edin.

Bridgwater, Nov. 19th, 1911.

To the Editor of THE LANCET.

SIR,—I hope you will find me space to reply to Dr. B. Hall's letter, which appeared in your last issue. Allow me to say, at the outset, that I am not endeavouring to prove that contract practice is necessarily more immoral and dishonest than private practice, but I do undertake to demonstrate the greater disadvantages of contract practice, both to patients and physicians, when compared with private practice. Further, I undertake to show the disadvantages of contract practice, not only where the premium is adequate, but where it is much more than the most miserly member of the profession could desire. This point is of extreme importance, for I am sorry to say I meet not a few medical men who hurl all kinds of epithets at the Chancellor of the Exchequer because he threatens to introduce the contract system, who, when one asks them if a 12*s.* or 15*s.* capitation fee would make the scheme reasonable, immediately reply, "Yes, yes." These people seem willing to sell themselves.

Dr. Hall maintains that contract practice is more lucrative than private practice. I am doubtful about this, but I will say here that I feel inclined to agree with him. I most decidedly disagree with him, however, when he suggests that contract practice is as satisfactory to patient and physician as private practice. I take up his points in detail. Dr. Hall says, "Those who contend for payment for work done under the Act intend, I presume, that there should be paid us a fixed fee for every visit." As far as I am concerned, Dr. Hall is wrong in his presumption. The fee does not require to be fixed, but will depend on the time and place of the visit, the quantity and the quality of the work done, the ability or inability of the patient to pay, just as it depends on such circumstances in any private practice to-day. Dr Hall is not to understand, however, that medical men

would necessarily subscribe to the scheme even when the fees are placed on this footing. The system of payment is not the worst feature of the scheme. A worse, perhaps the worst, feature is this, that a patient as soon as he has chosen his medical adviser, and a doctor as soon as he has chosen his patient, are to be bound to one another for *a definite* period of time, no matter what discord may arise between the two parties. No doubt an aggrieved person will have the right of appeal to the Local Insurance Committee, but very awkward situations may arise while an appeal is in progress; whereas in private practice a patient is free to throw up his physician at any time, and a like liberty belongs to the physician.

Let me quote fully the next important point in his letter. Speaking of payment for work done, he considers the payment as so much per visit, always so much, never more and never less. He says: "Thus the value of the service rendered has no limit in its variation to the fixed fee. In the same way one can see that though the fee is in some occult way supposed to bear relation to the income, or rather rent of the patient, the relation is anything but regular—so irregular, in fact, that it is foolish to call it 'relation' at all." If these words were applied by anyone to that clause of the national insurance scheme which deals (or will deal) with medical fees, they could hardly be more apt.

Dr. Hall next states that "under the *per capita* system the relation—of visit to fee—is absolutely scientific." Surely if work can be scamped in private practice it may also be scamped in contract practice. Nay, it will be scamped more easily, for the physician's fee is secure, at least for a time. I am sure physicians who have had experience of contract practice will agree with me when I say that the temptation to cut work is stronger in a contract than in a private practice.

Dr. Hall then proceeds to show that in the contract system one may foretell more accurately the number of births, deaths, or visits to be made than in the private system. I have found it as difficult to prophesy in the one case as in the other. The economical aspect of the contract system I purposely pass over, for I hold most strongly that it is not the economical but the ethical aspect of the insurance scheme which should now occupy our attention. I have not much doubt but that Mr. Lloyd George is prepared to yield on the six cardinal points of the British Medical Association, but he is keeping the concession up his sleeve till the right time comes, when they will act as a sop to the profession. Suppose he does yield, will the laugh be on our side? Not at all; the Chancellor will have wedded the medical profession to contract practice.

In the last paragraph of his letter Dr. Hall states that he prefers contract to private work. Be it so. I would like, however, to point out to Dr. Hall two very important reasons for the abolition of contract practice. Firstly, the very fact that in the private system there is no legal contract between a patient and a physician makes the bond between these two parties all the more beneficial and desirable to both. Secondly, the mental influence which a physician exercises over his patient—a very important part of treatment—is apt to become a vanishing quantity whenever the parties are bound together by rules and regulations.

I am, Sir, yours faithfully,

Harringay, N., Nov. 20th, 1911. R. S. MILLER, M.B., Ch.B.

To the Editor of THE LANCET.

SIR,—I have followed with interest the letters and articles which have appeared in the medical journals on the Insurance Bill. As an insurance medical man in the City, having no active interests in general practice, "contract" or otherwise, I can only hope if the Bill passes that the best interests of the profession will have been safeguarded by those in authority. The ordinary insurance man is credited usually as being a very keen individual, he sees business in everything. As soon as the Bill passes the country will be probably flooded with schemes and proposals of all kinds, especially from companies doing an industrial class of work. New small companies will spring up. Clubs and societies, solvent and otherwise, will be bought up or amalgamated for the formation of an approved society in connexion with the scheme of national health insurance contained in the National Insurance Bill now before Parliament. I am afraid that the profession will suffer as under the Workmen's Compensation Act.

Under the Workmen's Compensation Act the injured man had free choice of doctor, and now as a great concession under the Insurance Bill the members are to have also free choice of doctor. Can anyone who pretends to know anything about the Workmen's Compensation Act be ignorant of the fact that a vast number of claimants come under the observation of a "select" few of the profession? Medical men are, of course, entitled to their opinions, and some hold stronger views than others on the question of placing men on the funds of a society or club on account of illness, but who, with any experience of contract practice, is ignorant of what takes place when men are members of several clubs at the same time when each club has a different doctor? What will happen when they have the choice of a dozen or more doctors I would not like to hazard. There is a certain amount of *esprit de corps* amongst the members of most clubs; this for one thing will vanish under the new system, but an increase of malingering, one of the inherent evils of "contract" practice, must be expected from the Insurance Bill, no matter how amended or administered.

The Bill will do good by relieving the overcrowded outpatient departments of our large hospitals, tending to diminish abuse and incidentally help to get men back to work quicker. I examined a man twice within the past few months for one of the companies. He had a wound of the hand which had become chronic. He was under treatment at one of the London hospitals, where he attended once a week, getting a bottle of lotion with which he was instructed to bathe the hand daily at home. I asked him why he did not attend a private doctor, and he said he could not afford to do so, which I fully believed. On making out my report to the company I mentioned that in such a case under the new Bill the man would have been able to command the services of a private doctor, who would have probably seen the man every day or every other day, dressed the wound, and that in all probability he would have recovered in a few weeks instead of a few months.

If Mr. Lloyd George can only help us to get rid of the "Prescribing Chemist" and the "Dispensing Doctor" by the aid of his Bill he will have earned the everlasting gratitude of all who have the best interests of the profession at heart.

I am, Sir, yours faithfully,

London, E.C., Nov. 20th, 1911. J. J. SCANLAN.

*** Dr. Scanlan makes shrewd points in his letter, but his closing sentence confirms his statement that his personal interests lie outside general practice. Many practitioners do not desire to relinquish dispensing, and strong arguments have been supplied to show that what appears to be a progressive move may act badly for the public as well as for many practitioners.—ED. L.

To the Editor of THE LANCET.

SIR,—As a practitioner in Lancashire I was present at the meeting of protest against the National Insurance Bill held at the Midland Hotel, Manchester, last Saturday, Nov. 18th. I was very pleased to see on the platform so many of the leaders of the profession in the Manchester district, and I listened to their inspiring "die-hard" advice tendered to us general practitioners. We were told that no man who wishes to retain the respect and esteem of his professional colleagues must serve on the proposed panels or assist in any form to carry out the provisions of the National Insurance Bill, unless the six cardinal points demanded by the British Medical Association be conceded. When we hear such advice given to general practitioners by our leaders, the consultant physicians and surgeons, we feel that we have a clear lead given to us.

May we then assume that these leaders of the profession are prepared to stand with us and to refuse to consult with, or operate for, any man who takes office or works under the provisions of the Bill? Also, will they give their guarantee that they themselves will accept no post whatever under the Bill? If we could have such an assurance we should march forward with solid front in opposition to the Bill.

I am, Sir, yours faithfully,

Cadishead, Nov. 20th, 1911. E. O. JAGO.

To the Editor of THE LANCET.

SIR,—If this Bill passes without severe amending it will be a grave danger to the public health, and will perpetuate the worst evils of cheap hospital treatment, cheap dispensaries, cheap surgeries, and club practice. There are a few points I wish to call the grave and serious minds of doctors and others to.

1. Will this Bill permit the doctors and assistants working under it to come under the Workmen's Compensation Act? That Act applies to incomes under £250, and I am certain that the gross income of 65 per cent. of doctors does not now exceed £200. It will be less under the Bill, more especially if dispensing is taken from them—an item sometimes equal to more than half their income. Let a clause be introduced to provide for this.

2. Does the Bill guarantee to the doctor life tenure of office? It does not. We know the trouble that asylum, public health, and Poor-law doctors have over this. Tenure is here doubly important seeing the Bill now hands the doctors absolutely over to the Friendly Society and other club members on the Local Insurance Committee.

3. Does the Bill guarantee superannuation to doctors? It does not. The working classes have been given State superannuation of 5*s.* weekly. Almost all companies grant it. Why attack the doctors?

4. Does the Bill provide for payment of locum tenens when doctor is sick or on holiday? It does not. Here again the working classes are even now provided for, and will be more so if this Bill passes.

5. Does the Bill permit doctors, their wives, and families to insure against the benefits? This is doubtful, and should be cleared up.

6. How are we to find out the actual gross income of insured? About 885,397 persons, exclusive of firms and companies, pay under the income tax. How are we to decide regarding the 25,000,000 persons who will insure? Will the Income-tax Commissioners help?

7. How are we to find the gross income of "voluntary" persons under this Bill? Mr. Lloyd George in his book, "The People's Insurance," price 1*s.*, on p. 132, says: "The Governor of the Bank can join" as a voluntary member, and that he means Mrs. George and her children to join.

8. What should the payment to the doctor be per member? Recollect that we shall be called upon to treat rich and poor, young and old, strong and weak, cripple and sound, and those so ill that they *must* be Post Office members, those over 60 years. Also, that as the Bill refuses medical or sick benefits until four weeks after a confinement we shall have a large amount of waiting sickness thrown upon us. It means that the work of doctors will be trebled under the Bill and their pay lessened by half. I think we should accept a *minimum* of 10*s.* per member per annum of those who are "compulsorily" insured, and for "voluntarily" insured of £160 income. This sum for each man, woman, child, and maid would work out at about (four children per family) 70*s.* per family per annum; not a large sum for good, efficient treatment.

9. Should doctors, on the other hand, be paid per visit? A few may recollect that in the *British Medical Journal* of June 22nd, 1889, I proposed the formation of a public Medical Service of England, while in the *Foresters' Miscellany* for August, 1886, I gave a very full account of the German insurance against sickness, accident, infirmity, and old age. I am more than sorry that the doctors in the British Medical Association did not adopt my proposal, as it would automatically have swept away club practice and would now have avoided all the present trouble, as we would be in a strong position to offer our services at a fixed price and so really be business men and not mendicants.

10. The confinement fee should be 42*s.* for the first and a definite fixed fee for instrumental and manual labours. At present the idea of the Bill is to be one of State subsidy to midwives. It is said that last year midwives conducted half the total confinements, this meaning a lessened income on the year of about £440,000 of doctors.

11. Will the doctors acting at voluntary hospitals be granted an income for treating sick assured members? Each should be paid a *minimum* of £500 yearly. After very arduous work I have collected statistics showing that not less than 4,136,263 persons in the United Kingdom during 1901 obtained medical, surgical, and midwifery relief, or 1 in 11 of the entire population, at the voluntary hospitals alone; that is exclusive of clubs, asylum, fever, Poor-law, and other hospitals. As showing the money value of this treatment, if we estimate it at 10*s.* per person, including all operations, here is a money loss to doctors of not less than £2,068,131. Of course, the loss is ten times this, owing to our checking sickness, deaths, and chronic invalidity. Under this Bill the hospital patients will be doubled, just as they have been greatly increased by cheap club practice. Why therefore, cannot the State pay doctors, as it will pay well the other officials under this Bill.

12. The Bill does not provide a scale of fees for surgical operations. Why not? Under the Poor-law regulations there is a scale of fees for operations, confinements, and vaccination.

13. The Bill does not provide for dental treatment. This is perhaps one of the grosser defects of the Bill. I have estimated that £4,500,000 would duly provide for this most important feature of sickness and malnutrition.

14. Should doctors surrender dispensing to assured members. At present 60 per cent. of the income of many doctors is derived from dispensing. In their present chronic condition of genteel poverty, can they afford to make the chemists a present of it, and if not, will the chemists purchase the goodwill, and so recompense the doctors? I have proposed that the chemists form a sinking fund, taking it off the sick members of, say, 1*d.* per prescription, so as to purchase out the rights of doctors.

15. How many members to each doctor? This is the basis of the Bill to us, for if we are not very particular political trickery will come in, and so those doctors on the "wrong side" will not be "fed" by the local secretaries. A limit would also lessen bribery of many kinds. If each doctor could secure 1000 members at 10*s.* each, this would give £500 to each. But this high average cannot be obtained, as the army, navy, police, and all the civil service, as post office, telegraph, telephone, customs, inland revenue, will remain as they are. In 1901 there were 22,695 doctors *practising* in England and Wales, or on a gross average of 1 practitioner to 1433 persons (see also report of the General Medical Council of 1886 upon these averages). Suppose half the population become members, this gives 16,263,921 members, and at 10*s.* per head a gross sum of about £350 per doctor per annum. Now when we deduct income and other taxes, conveyances, servants, part rent, and other items, it is impossible to see how doctors can for this pittance supply efficient medical treatment. The midwifery fees, with a steadily falling birth-rate—a rate which will soon fall to 12 per 1000—and with midwives employed, must not be counted upon.

16. Unemployment benefit to pregnant women. Our employing pregnant women in factories and mills has become a public laughing stock, an object of scoff and satire. Similarly with their re-employment four weeks after confinement. Thus the horrible and devastating maternal sick- and death-rates, and the juggernaut of infant murders—given out to be "nursed" on tea; and their deaths, encouraged by insurance. The want of such provision in this Bill—one whose promoters have the bluffing effrontery to officially describe in its preamble as one "for the prevention and cure of sickness"—is enough to hiss it out of existence in its present form, and to fit it for comic opera, were there not so terrible a tragedy in it.

This Bill cannot be administered honestly and with due consideration for the health of mothers and infants—the basis and backbone of national health—without the active approving help of doctors. It is for this reason I advise them seriously to have nothing to do with it, and to give their reasons to the sick and future sick public. A well medically administered Act would pull down the death-rate by 5 per 1000, the sick-rate by 50 per cent., and lessen the expenses of administering the Act by at least £5,000,000 annually.

I am, Sir, yours faithfully,

Liverpool, Nov. 14th, 1911. ROBERT R. RENTOUL.

To the Editor of THE LANCET.

SIR,—The previous letter and the one which appears in to-day's issue of THE LANCET on the above subject from the pen of Sir A. Pearce Gould appear to me to be so much to the point and so unanswerable that I am puzzled that the profession as a whole do not, before it is too late, abandon what, in my opinion, is a very untenable position and adopt the simple, and I think sound, principle of "payment for work done." I confess I find it difficult to understand the

mental attitude of those who can find anything to say in favour of the "contract system." My experience of such practice is comparatively limited, but I think I have seen quite enough of it to satisfy myself, at least, that it can never be satisfactory to either of the parties concerned. A couple of days after the introduction of the Bill, when I saw that the Chancellor of the Exchequer was proposing to perpetuate and to give State sanction to a system which was almost universally condemned, I, as one of his constituents and supporters, took the liberty of writing to him, regretting the proposal he had made, and saying I thought I could suggest a much more satisfactory plan of remunerating medical men. By the time I received his reply the profession had made what I cannot help considering a very regrettable *faux pas*. I venture to say that the plan advocated by Sir A. Pearce Gould and others will be found in practice to be simplicity itself. It differs in no essential particular from private practice, except that payment will be much more certain.

At first sight, however, there are two dangers: first, that some doctors may be disposed to run up a bill unnecessarily; and, second, that some patients may be too often on the sick list. These two really resolve themselves into one, and can be easily guarded against at one and the same time by docking the weekly payment of the patient after the attendances have exceeded a certain number. In this way both doctor and patient are checked at the same time.

I am, Sir, yours faithfully,

Bangor, Nov. 18th, 1911. RICHD. WILLIAMS.

To the Editor of THE LANCET.

SIR,—Cannot a modification of the capitation system be devised that would make it acceptable to the medical profession?

Firstly, a minimum sum per head must be fixed upon and put in the Bill. As this minimum means in all cases a maximum, it must be sufficient to avoid disputes between the profession, when split up into small bodies, and the Local Health Committees.

Secondly, the Chancellor in his opening speech laid great stress on the fact that when funds accumulated, as they would do, additional benefits would be extended to the insured in the way of increased sick pay, &c. No word, mark you, of increasing the pay of the medical men, through whose exertions the funds accumulated. Now, why not give medical men a direct interest in the measure by increasing their pay in an equal ratio? Sick pay goes up to 12*s.*, then an extra shilling per head to each doctor, and so on. In such a way we would have an incentive to give our best service and look keenly after any malingering. As long as human nature is as it is some such tangible inducement is probably necessary.

I am, Sir, yours faithfully,

Nov. 20th, 1911. W. ROBERTSON.

To the Editor of THE LANCET.

SIR,—I shall be grateful if you will permit me to direct the attention of medical men to the fact that a list is being compiled of medical men who are in favour of having medical benefits included in the Irish Insurance Bill. I therefore request that all medical men desirous of having medical benefits applied to Ireland will without delay send me their cards or postcards, bearing on them their signatures and the words "For Medical Benefits." When the list is complete it will be forwarded to the Chancellor of the Exchequer as evidence that Irish practitioners approve of the application of medical benefits to this country.

I am, Sir, yours faithfully,

SEYMOUR STRITCH.

13, North Frederick-street, Dublin, Nov. 19th, 1911.

To the Editor of THE LANCET.

SIR,—I think those who desire payment by a capitation fee are sufficiently answered by Mr. Lloyd George's statement in Parliament on Nov. 14th, when he said the demand of the Irish Medical Association for a capitation fee of 8*s.* 6*d.* was "financially impossible," and that 6*s.* might be taken as the "financial basis" of the Bill—that is, 4*s.* 6*d.* for the doctor and 1*s.* 6*d.* for medicines, &c. Truly a princely sum!

Surely the demand of 8*s.* 6*d.*, exclusive of medicines, &c, is little enough, even to those who wish for this method of perpetuating the hated club system. I might add that the financing of the scheme is no business of ours. The Bill is forced on us and we demand, not petition for, what we consider is our due, and unless we obtain it we absolutely refuse to work under the Bill.

I am, Sir, yours faithfully,

Heaton Park, Manchester, Nov. 20th, 1911. E. T. LARKAM.

To the Editor of THE LANCET.

SIR,—It may seem absurd to remind your readers that a part is not equal to the whole. That it is not superfluous, however, to do so is clearly indicated by the confusion that has arisen over what constitutes "contract" practice, especially in relation to the Insurance Bill. This confusion, due to transference in thought to the whole of qualities that belong necessarily only to a part, is plainly instanced in the letter of Dr. B. Hall published in THE LANCET of Nov. 18th. Dr. Hall there says: "In my letter of Nov. 4th I referred to the fact that a considerable percentage of medical men is now, and has been for generations, working on the contract system in which payment is by salary. Surely everything that can be said against the *per capita* system applies to this system of payment by salary." That is exactly what it does not do, and it is the inability to see why it does not, that is creating much confusion and waste of argument, and causing many outside of the medical profession to wonder at its determined opposition to what would appear at first blush to be a reasonable and, provided the *per capita* payment is "adequate," a profitable plan.

It is a fact that the *per capita* system of payment, so far as medical service is concerned, is radically and essentially bad, and that quite independently of the amount of any probable *per capita* payment. "Why," it may be asked, "is a plan which works well with other occupations necessarily bad in the practice of medicine?" The answer is simple. Because the services demanded of the medical practitioner are entirely different in kind and in character of obligation from those of any other occupation or profession. They are imperative on the score of humanity, and there can be, in consequence, no arbitrarily fixed limitation set to the amount of service that may be demanded at a given time of each individual practitioner, or to the time at which or the hours during which he shall be required to labour.

This fact may be best brought out by a consideration of what actually happens in the course of (1) private practice; (2) so-called "club practice"—i.e., contract practice based on a *per capita* payment system; and (3) salaried contract practice, of which the naval and military medical services may be taken as the best known and highest types.

Private practice has this in common with "club practice," that the medical attendant is the employee of each of his individual patients. The *primâ facie* claim of all patients on the doctor's services is equal. Priority of service can be demanded only on the score of priority of summons or of obvious urgency. If two or more patients happen urgently to need the medical man's services at the same time, he attends to the first-comer first, and later, to all subsequent comers in turn—there are no closing hours for the doctor—provided they have not already betaken themselves elsewhere for assistance, which in private practice is not unlikely to happen. In the latter event these patients do not have to pay the medical man for what they have not had. The fee that would have been his, had he attended them, goes to the doctor who actually did attend. Moreover, having a fee to pay for each separate act of service rendered, the patient is not so apt to summon his medical attendant unnecessarily, and even if he did, it would be doctor's right, when already overtaxed, to forego his fee and refer the patient to some other medical man.

In club practice, on the other hand, each patient has already paid the appointed club doctor—or the one he may choose from an authorised panel, if any—for every service that can be demanded from him during the currency of his subscription. If a number need him simultaneously or in rapid succession, each has theoretically an equal right to his instant service, for all alike have paid him

equally. Supposing that in the presence of some case of serious emergency the better-disposed patients are content to yield place until he has done with the urgent case, they merely postpone their own call on his services, and expect him, and rightly so, at once to direct his attention to them. Thus a string of claims upon his time and strength may, and often does, accumulate in such a way that for long periods together the doctor is deprived of proper time for repose, for meals, or for leisure for recreation or study, the first of which is essential for the continued performance of good work, and the second necessary in the public interest. The medical man in private practice can, if he chooses, and he often does, decline to take more obligations than he can adequately fulfil without undue strain on his health and reasonable comfort. Those that he cannot attend when need arises are free, without being mulcted twice for the same service, to seek aid elsewhere. But in club practice it is not so. Having taken a number of *per capita* payments by contract he is bound to fulfil his obligations with equal loyalty to everyone, regardless of the cost to his own health and well-being and of the results to his own family life. And although the club or Government authority is not his real paymaster it will insist on his performing to the full the duty he has undertaken. When one or the other—the doctor or the patient—must suffer, its sympathy is practically always on the side of its own *protégé*, of whose interests it is the custodian.

Now let us look at the difference between *per capita* club practice and salaried practice, let us say, in the army. Both, it is true, are "contract" practice. But the army doctor enters the service as the employee, not of each individual patient, but of the Government which pays him. He arranges terms and conditions of service—or rather accepts those which the profession has secured for him—not with 1000 masters having different, often conflicting, interests, but with one master. He is responsible, not to his patient, but to his employer, the Government. His employer, advised and represented by his superior officers in the service, knows what is humanly possible in the way of labour and what is not. It realises—sometimes, it is true, not until it has had a rude lesson—that to get the right kind of men, competent and willing to do the work, it must make the terms of its service attractive. It arranges for him his hours off duty, during which under ordinary conditions no work can be demanded of him, thus securing to him time for repose, leisure, and relaxation. He is assured of social position and of a certain amount of social life. Provision is made for increase of pay and rank with years of service, and his future is provided for by either a pension or a retiring allowance at his choice. Opportunity is periodically afforded him by leave on full pay for both recuperation and professional study. His work is thus collected into one consistent whole under one master, to whom alone he is responsible. How different is the case of club practice! Here the practitioner's obligations are distributed among many distinct individuals with necessarily conflicting interests, to each of which he is personally responsible as to a different master. To this fact are traceable all the intolerable results of the club system—the inconsiderate demands, the frivolous complaints, the exactions, the incessant grind, resulting in an overworked and often underfed, or at least improperly fed, doctor, who cannot himself carry out the very precepts it is his duty to instil insistently into others. What wonder that his *clientèle* in its turn should suffer from scamped work, inadequate care and attention, waning skill through lack of opportunity for study, and the absence of that magnetic sympathy between doctor and patient which is half the battle in the struggle with disease.

The question of a salaried medical service under the Bill need not be discussed, for there are other and more practicable plans, as, for instance, that suggested by Sir Alfred Pearce Gould in THE LANCET of Nov. 18th. The point is, that whatever other methods of payment may be found suitable, a *per capita* payment, which renders the medical man a slave to the caprices of a number of distinct and independent masters, is radically bad, as has hitherto been consistently held by the profession at large. Certainly a method that is radically bad for the medical profession—and through them for the individual patient and the public at large—ought not to be made compulsory.

I am, Sir, yours faithfully,

Nov. 20th, 1911. EXPERTO CREDE.

"SPONGE EDUCTION."

To the Editor of THE LANCET.

SIR,—I have read with great interest the annotation on "Sponge Eduction" in your issue of Nov. 11th, p. 1348, and note the remark that the method seems to have originated in America.

The late D. J. Hamilton, professor of pathology in Aberdeen University, was one of the earliest workers on the subject of "Organisation of Porous Dead Materials," and advocated the use of sponge in accelerating the healing of indolent ulcers. His method was somewhat different from that described by Dr. E. Ward, inasmuch that thinner layers of sponge were used, and that instead of pulling on the sponge when filled with organising vascular tissue, a second layer was applied. It may be of interest to quote his plan as described in his "Text-book of Pathology," published in 1889:—

> The wound should first of all be rendered aseptic, and any sloughy shreds should be got rid of. A close-meshed Turkey sponge is the best for the purpose. It should be cut into thin sections in the freezing microtome, and the larger they are the better. The sponge should be wrung out of freezing fluid "A," and be stuck on the freezer with mucilage. The sections should not be more than from 1/16th-1/32nd of an inch in thickness and may be applied in one large continuous piece or in several small ones. Great care should be taken that the sponge does not come nearer than 1/8th to 1/4th of an inch from the epithelial edge or the latter will be sure to undermine it and prevent its adhering. In a few days it will be found to be filled with organising vascular tissue. A second layer considerably smaller than the first should now be placed on the surface, followed by a third, and so on, until the wound is healed. Indolent ulcers take on a remarkably healing and healthy look within a very short time of its application. The sponge before being cut must be soaked in a dilute solution of caustic potash for several hours, and subsequently in a dilute solution of nitric acid for a night. It should be thoroughly washed in water after this and the sections may be kept in watery solution of carbolic acid (1 to 40) until required. The dressing should be strictly antiseptic, the ordinary dextrine silk forming an excellent protective covering. Freezing fluid "A" is composed of 4 parts of a syrup, containing 28·5 grm. of pure sugar to 30 c.c., 5 parts of a mucilage of gum acacia of the strength of 45·6 grm. of gum to 2400 c.c. of water and 9 parts water. The whole boiled and saturated while hot with boracic acid and filtered when cold through muslin.

Hamilton's experiments were published in the *Edinburgh Medical Journal* in 1881 and were confirmed by Marchand later. As regards the fate of the sponge in the tissues, Hamilton, on examination of parts in which a piece of sponge had become ingrafted, could find no trace of it, and concluded that the keratode of which it is composed is absorbed after fulfilling its mission as a framework for the tissues to grow in.

It seems to me that Hamilton's method is to be preferred to the more recently described one, because one would be more likely to get a firmer pad when the framework for the granulations to grow in is left until absorbed instead of being pulled away.

Of course, one would not reduce the size of each layer of sponge, as recommended by Hamilton, if it were desired to build up a wound as in the case of a lacerated finger.

I am, Sir, yours faithfully,

Banff, Nov. 13th, 1911. WM. MANSON FERGUSSON.

RECENT DEVELOPMENTS IN THE RECOGNITION, TREATMENT, AND PROPHYLAXIS OF SYPHILIS.

To the Editor of THE LANCET.

SIR,—In reading over the report of his first Hunterian lecture I notice that Major H. C. French quoted me as having stated that I "only succeeded in demonstrating the spirochæta pallida in 152 out of 202 cases of syphilitic sores" and as having suggested "that in the remaining 25 per cent. of cases local antiseptics or other causes may have prevented the demonstration." This does not convey the impression I intended, as is shown by reference to the original paper,[1] in which I stated: "I may mention that out of 202 syphilitic sores which I have examined I have established the diagnosis by means of the dark-ground apparatus in a few minutes in 152. I think this number would be much larger if in 40 out of the remaining 50 cases an antiseptic had not been previously applied to the sore. In a number of the 152 cases in which the diagnosis was made so rapidly

[1] Brit. Med. Jour., Sept. 23rd, 1911, p. 686.

I have had the opportunity of submitting the sore to examination by expert clinicians, who confessed that on clinical grounds they would not have taken the responsibility of diagnosing them as syphilitic."

I am, Sir, yours faithfully,

L. W. HARRISON,
Major R.A.M.C.

Rochester-row, S.W., Nov. 15th, 1911.

FEES TO SHIP SURGEONS.

To the Editor of THE LANCET.

SIR,—Referring to the letter on the above subject from Dr. R. R. Rentoul, the writer must not be too "glad" at escaping the thanks of ship surgeons, as his escape is possibly due to their ignorance of his endeavours on their behalf. Some 16 years ago Dr. Dutton brought the subject of charging passengers the usual fees for medical attendance to the notice of shipping companies; eleven years ago I approached the P. and O. Company on the same matter, and a little later Dr. Elder worked on similar lines. It is therefore not altogether surprising that some of us were ignorant that it was to Dr. Rentoul and his efforts five years ago that all our thanks were due.

Dr. Rentoul warns us that a few surgeons are helping to ruin his proposal—he does not say what that proposal exactly is—by objecting to submit their bills to the captain. I have met a great many ship surgeons; to their credit all of them do object to this practice, most of them feeling that the relations between patient and surgeon are confidential and concern no one else. We should all be glad to know with what object such a rule was made. Is it that the accounts may be revised and criticised by the commander? Or is it to check abuse? If for the former purpose, it seems an unwarrantable interference; if for the latter, it is not quite complimentary to the surgeon. Perhaps Dr. Rentoul may be able to enlighten us on the real object.

I am, Sir, yours faithfully,

T. W. ATKINS.

Nov. 22nd, 1911.

ELECTION OF DIRECT REPRESENTATIVES ON THE GENERAL MEDICAL COUNCIL.

To the Editor of THE LANCET.

SIR,—We wish to take the earliest opportunity of thanking most sincerely every one who has supported us at the recent election, in which we have been returned by so handsome a majority; and we feel particularly grateful to those busy workers who, having little leisure, yet have found time to attend committees and meetings, and to do all in their power to further our candidature.

We are, Sir, yours faithfully,

HENRY W. LANGLEY BROWNE.
H. A. LATIMER.
T. JENNER VERRALL.

Nov. 20th, 1911.

UNIVERSITY COLLEGE HOSPITAL: A LECTURESHIP FOR MEDICAL RESEARCH.—This hospital has received from Mrs. C. Kayler a sum of £1000 to found and endow a lectureship in memory of her father, the late Dr. Sydney Ringer, formerly consulting physician. The lecturer will be selected every two years, and will take as the basis of his lecture original research carried out by him in the physiological or pharmacological laboratories of University College or in University College Hospital Medical School.

A BALL will be held in the New Banqueting Hall, Savoy Hotel, London, on Wednesday, Nov. 29th, in aid of the funds of the Army and Navy Male Nurses' Coöperation. The object of this coöperation is to afford to the public thoroughly well-trained male nurses and sick attendants of good character, and to provide employment for retired non-commissioned officers and men of the Nursing Section of the Royal Army Medical Corps and members of the Sick Berth Staff of the Royal Navy. Tickets—price, 1 guinea each; for parties of four or more, 15*s.* each—may be obtained from Mrs. Frank Juler, 24, Cavendish-square, London, W.; or Miss Ethel McCaul, honorary secretary, 11A, Welbeck-street, Cavendish-square, London, W.

THE DEMAND FOR PUBLIC ABATTOIRS.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Concluded from p. 1435.)

FAILURE OF ABATTOIR REFORM AT LIVERPOOL.

Defects of the Birkenhead Foreign Cattle Lairage.

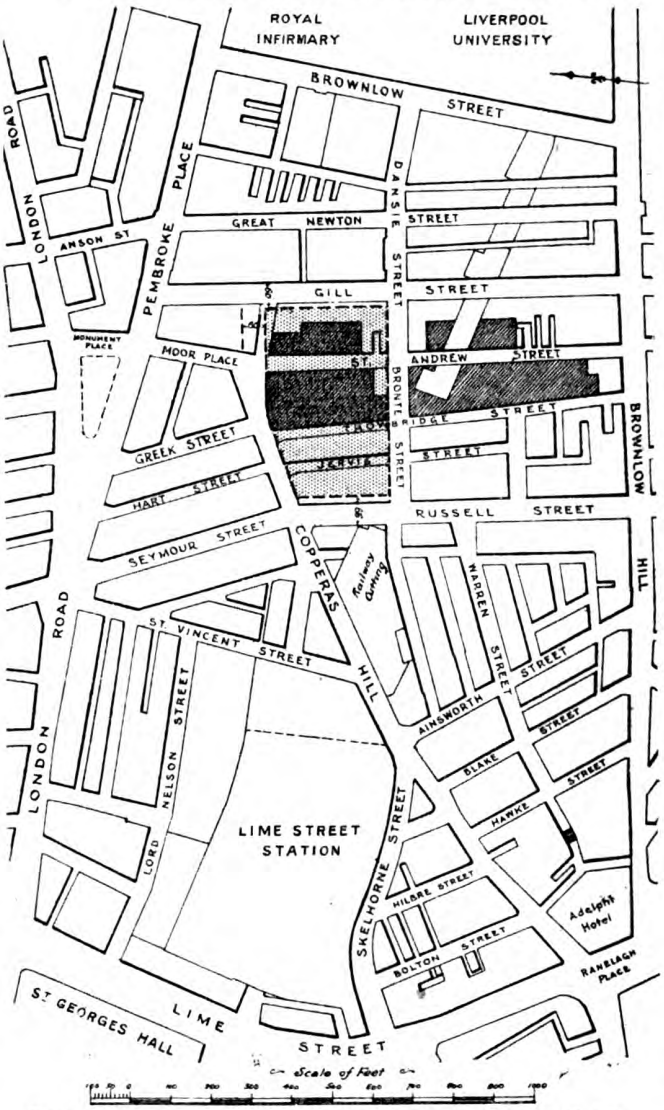
LIVERPOOL has not been particularly successful in solving the slaughter-house problem. First and foremost, it has allowed a gigantic business in the slaughtering of foreign cattle to go to the other side of the Mersey, though there were no proper slaughter-houses at Birkenhead. Even to-day it cannot be said that the lairage and the abattoir provided for the foreign cattle at Birkenhead fulfil modern requirements. Without entering into details, the fact that old factories or mills have been converted into slaughter-houses is a sufficient condemnation. A slaughter-house must be specially designed and constructed; existing buildings cannot be adapted for that purpose. If when the foreign cattle trade gave promise of expansion the corporation of Liverpool had built a large model abattoir the meat industry might not have passed over to Birkenhead. To the nation at large, of course, it does not matter on which side of the Mersey the foreign cattle are landed and killed. But the public is interested in seeing that this is done in abattoirs where every facility exists for the inspection of the meat and its cleanly handling. At Birkenhead there is an insufficient staff of inspectors. The principal inspector admitted to me that he did not see all the animals at the moment of killing, but urged that if he found a diseased viscus he would know to what lot of cattle it belonged and would hunt out the carcass. In so important a place as the Birkenhead foreign cattle lairage and slaughter-house there should be several veterinary surgeons on the spot, and no viscus should be separated or removed from the animal till it is inspected.

Mills Converted into Abattoirs.

Considering that a large trade in the importation of American cattle has grown up at Birkenhead on premises absolutely unsuitable for the purpose, and where the control is of the crudest, it is surprising that the city of Liverpool should not have attempted something better. The rival city of Manchester, in any case, did not lose the opportunity. As soon as the Ship Canal was built, enabling ocean steamers to reach Manchester, the Foreign Animal Wharf at Old Trafford was constructed. Though this establishment is not perfect in all respects, as I explained in my last article, still it is a real lairage and abattoir. Everything was planned for this express purpose, while at Birkenhead there are no such buildings. In this latter place cattle are driven to the upper floors of the old warehouses or mills. Instead of a lairage the cattle are lodged upstairs, and the dirt they make is drained out through a window into a big pipe suspended in mid-air. On the ground floor the cattle are slaughtered. Instead of air and light coming from the roof of the killing floors, there is no light, no air from the roof, because there is no roof; it is a ceiling and not a roof, and it is a watertight ceiling, because there are cattle on the floor above. That does not help to ventilate or to illuminate the place. It is astonishing that a proper wharf, lairage, and abattoir have not been built in some other part of Birkenhead. Liverpool, however, makes no attempt to draw the trade to its side of the Mersey.

Abattoir Nuisance in the Heart of Liverpool.

The strange thing is that the need of a proper abattoir at Liverpool has been acknowledged for many years. The butchers themselves at the beginning of the nineteenth century already realised that it was better to work together than separately. As previously related in these columns, they grouped together several businesses and established in the centre of the town a joint abattoir.[1] In those days there was no knowledge of the dangers that accompany the butcher's trade, but of recent years the corporation was obliged to buy out all the private butchers and convert their joint slaughter-house into a municipal abattoir. The premises, however, are so unsuitable for the purpose that killing was discouraged, and now a part of the slaughter-houses has been converted into a meat market. Still there



[1] THE LANCET, August 22nd, 1908, p. 586.

is some killing done here, especially of sheep. Then there is a horrible place it was my misfortune to visit where putrefied or condemned meat and carcasses are kept till such time as they can be removed to the destructor. The stench is sometimes appalling, and this abomination is barely 110 yards from the Liverpool University and the Royal Infirmary. Both these buildings also are on a higher level. It is incredible that such an industry should be allowed close to and between the hospital, the University, and the principal railway station and hotels of the town. The sanitary authorities of Liverpool have insisted over and over again that an abattoir, especially such an antiquated and insanitary abattoir, should not be allowed to stand with the University and hospital so close on one side, and on the other side St. George's Hall, Lime-street station, the theatres, hotels, museums—in a word, the magnificent centre of which Liverpool is justly proud. Dirty work is done at the abattoir. Apart from the killing, hide sorting and salting do not make up an ideal occupation. The offal, the intestines, the manure, the diseased carcasses, and the putrid meat have to be handled and carted from the abattoir through the streets, and the animals destined for slaughter are driven along the same streets to the abattoir. All such traffic should not take place in the very heart of the city. The whole business should be removed to an open, airy suburb where there are few or no inhabitants.

The Private Slaughter-houses of Liverpool.

The construction of a proper abattoir on a suitable site would be the more easy, as there is no reason to fear competition from the butchers. There used to be 25 private slaughter-houses at Liverpool, and these are now reduced to 17. The corporation has very wisely refused to grant any more licences. Some of the private slaughter-houses have only annual licences, and these could easily be stopped. Even if legal sanction for the compulsory closure of the remainder, which are worked on life licences, could not be obtained, they do so little work that their competition would not interfere with the prosperity of a model municipal abattoir. In visiting some of the private slaughter-houses I came across the butcher who supplies the highest classes in Liverpool with the best meat. For slaughter-house he utilised a small barn. The floor, however, was of flagstones draining to a gully. Formerly there was a big cesspool in the middle of the barn. Now this has been filled up and concreted and the place drains into the sewer. But when first built the barn was in the suburbs and probably there was no sewer. To-day it is considered to be in a central district. Nevertheless the slaughtering work continues, though there is only inadequate equipment. The best use is being made of the buildings that is possible in the circumstances, but they are unsuited for the work. For absolute lack of everything that is needed it would be difficult to surpass the wooden shanty belonging to the breeder of celebrated pedigree pigs. So wonderfully and fearfully made is this structure that I implored Dr. Hope to take a photograph so that future generations might know what was still tolerated at the beginning of the twentieth century. Dr. Hope's annual reports on the health of the City of Liverpool are rendered more interesting and instructive by numerous photographs. These supply precious testimony as to the insalubrious condition of much property that has now been reformed out of existence. But the private slaughter-house in question still exists, and to my great joy I found that a photogravure of it had appeared in the medical officer's report for 1909.

SITE OF PROPOSED PUBLIC ABATTOIR FOR LIVERPOOL.

Dotted area indicates proposed site under a scheme which should not find favour; it is too central; black area shows present abattoir buildings. Note the nearness of the infirmary and the University at the top of the map, and of St. George's Hall and the fine centre of the city at the bottom. (Reproduced from the corporation surveyor's scheme.)

Slaughtering in a Shanty.

In many respects, except in regard to the slaughter-house, or shanty as it should be called, its owner has manifested a keen appreciation of the beneficent effects of good sanitation. The housing of the pedigree pigs is perfectly ideal. First of all every pig is carefully and frequently bathed, then he is allured into a luxurious stall which he enjoys all to himself, though it is as big as a horse stall. The floors are of concrete, the walls are well lime-washed, and there are eight louvred windows at the back of six stalls. Opposite, the upper parts of the doors open like windows to admit fresh air from a large field. So much light, ventilation space, and continual cleaning is rarely provided for human beings; but then these pedigree pigs can readily be sold for £30 each. All this lavish expenditure and supreme carefulness over living pigs made the contrast with the slaughter shanty the more marked. Instead of solid walls with louvred windows there were a few planks nailed together, and some tar to save them from rotting too quickly. The roof is so low that the lowest portion is only 4 ft. 6 in. from the ground. Not one but all the walls are of wood, whitewashed inside and tarred outside. To call this a slaughter-house is quite

preposterous. It is such a ramshackle structure that it seems incapable of bearing the weight of a good heavy bullock if strung up to one of the dust- and dirt-laden rafters within. But bullocks are killed here and they do not drag the building down with them. Nevertheless, this should not be allowed, particularly as the shanty abuts on a high road and there are dwelling-houses close at hand. The pavement outside the shanty is most irregular. Old bits of broken asphalte have been thrown over one part and have formed themselves into strange-shaped lumps. In another direction there are nubbly stones, but in all directions the water mixed with blood and manure from the slaughtering of animals filters down easily into the subsoil to create a permanent condition of impurity. The intestines and useless offal are removed at night to the farms, but tubs get impregnated, and porous wood is not the right material to hold such organic matter. There is no thought given as to modern processes and the scientific apparatus now used for speedy and cleanly work.

Liverpool Corporation Studies Continental Abattoirs.

The existing evils, fortunately, are fully admitted. Nobody attempts to apologise or to find extenuating circumstances so as to justify their continued existence. On the contrary, the corporation has appointed a special sub-committee, consisting of Sir Charles Petrie, several aldermen and councillors, the town clerk, the corporation surveyor, the city engineer, the superintendent of markets, and the medical officer of health. These gentlemen have proceeded to the continent so as to study and report upon the importance of centralising the live cattle markets, abattoirs, dead meat markets, and the allied trades on one site. Of course, there were also many technical matters for them to investigate. The committee started on their journey in the spring of 1909, and they visited the abattoirs and cattle markets of Brussels, Cologne, Frankfort, Munich, Vienna, Dresden, Berlin, Budapest, and a few English abattoirs. On their return they issued a report with many illustrations. This report shows that they were greatly impressed by the large amount of land devoted to the abattoirs and cattle markets of continental towns—32 acres at Brussels and 93 acres at Berlin. Then they note that the abattoirs were outside the towns and had such railway accommodation as rendered it unnecessary to drive cattle through the streets. Of course, the immense superiority in structure, in methods of inspection and handling meat, did not fail to impress the Commission. Then came the great practical fact that though the cost varied from £400,000 at Cologne to £800,000 at Dresden, these abattoirs are self-supporting. After such an object lesson, all the Commission could say was to urge their fellow citizens of Liverpool to go and do likewise. For a moment it was thought that this excellent if obvious advice would be followed. Liverpool would then have, close to the river as part of the port and in touch with the railway and canal system, a central cattle market adjoining a modern model abattoir, with annexes for the treatment of all the by-products. All this would be so modern, so scientifically contrived and controlled, that it would provide the ships in the harbour and the population in the town with a safe, reliable meat-supply, while realising such profits as to give relief to the overburdened ratepayer. But it was not to be. Prejudices, apathy, the timorous feeling that perhaps somebody might lose something, stood in the way, and the proposals made were rejected. Much to the detriment of the interests of the city, the whole affair is once again in the melting pot. Several members of the Special Commission who went abroad and thoroughly studied the question have resigned out of disappointment. That is why to-day Liverpool, like Newcastle, joins in the demand now spreading from town to town for public abattoirs—not a mere tinkering with the question, but complete abattoirs with cattle markets adjoining, such as in Germany have proved of great benefit to the health of the people and the finances of the municipalities.

ROYAL METEOROLOGICAL SOCIETY.—The council of this society has awarded the Symons gold medal to Professor Cleveland Abbe, of the United States Weather Bureau, in recognition of the valuable work which he has done in connexion with meteorological science. The medal will be presented at the annual meeting of the society on Jan. 17th, 1912.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Medical Inspection of School Children.

THE recent report of Sir George Newman, medical officer to the Board of Education, on the great good which has resulted from the systematic medical inspection of children attending public elementary schools has prompted the inquiry as to what is being done and has been done in Manchester in this direction. An immense amount of good work is being done by the schools medical officer and his assistants. The statutory obligation has been carried out with great thoroughness, and must be productive of immense and lasting benefits to the children of the poor. The cost of elementary education to the ratepayers has been increased by about £14,000 by the extra duties imposed by Parliament, the duties including the care of the feeble-minded and other weakly children and the feeding of necessitous scholars. There are nearly 200 schools in the city, attended by about 120,000 children. The all too common defects of sight and hearing, the state of the teeth, uncleanliness, and diseases of the skin have to be constantly attended to. In special cases—last year over 4000—examinations were made by the school medical authorities at their offices, and the condition fully investigated. These cases had previously been seen by the medical officers at the schools. These special cases are of very great importance, and their investigation and treatment necessarily occupy a large amount of time as compared with what are called routine cases.

Purchase by South Manchester Guardians of Mansion and Estate for a Convalescent Home.

A notable advancement in Poor-law administration in Manchester has been achieved in the partial solution of two grave problems which face guardians here as elsewhere. How can the white plague, which largely helps to fill and overcrowd our workhouses, be arrested; and how can recovery of the sick poor be furthered so that they may be able to return again fit for work? The Local Government Board has approved of a scheme proposed by the South Manchester guardians for acquiring a mansion and an estate in the neighbourhood of Abergele, in North Wales, for the treatment of convalescents and of sufferers in the first stage of consumption. Naturally there was considerable opposition offered by the local governing bodies of Abergele, but this has been overruled. At the present time the South Manchester board of guardians has to find accommodation for its convalescents in institutions in all parts of the kingdom at a cost varying from 2 to 3 guineas a week, the average number of cases running to about 50. Consumptive patients who have reached the stage when the disease is contagious will not be sent to Abergele, and the institution there will not be an infectious diseases hospital in any sense of the word.

Smoke Abatement Exhibition.

This exhibition, promoted by the corporations of Manchester and Salford, was officially opened on Nov. 10th with a view to enable the public to inform itself of the means whereby the emission of smoke from chimneys can be reduced, if not actually abolished, so as to obtain a purer and more wholesome atmosphere in which to live and breathe. Apart from the bad effects of smoke and other products of industrial manufactures and house chimneys, the pecuniary loss is very great. It is calculated that smoke costs Greater Manchester £1,000,000 a year. To householders also a special appeal for the diminution of "home-made smoke" is made by the exhibition of apparatus for the more extended use of gas, electricity, and smokeless solid fuels in the domestic kitchen. Open kitchener grates at present in use are said to be responsible for nearly 60 per cent. of the total smoke poured out over the city. If this be so the sooner the citizens themselves take up the reform the better. There is a "gas home" and an "electric home" showing how these two agents can be successfully, effectively, and economically employed for domestic purposes.

Appointments of Women by Boards of Guardians.

At a meeting of the South Manchester board of guardians held on Nov. 10th it was proposed "That it be a rule in future that one of the three resident medical officers shall be a woman." The motion was not carried. It was not felt

desirable to tie the hands of the board as to its policy, while one woman representative favoured the making of appointments solely according to the qualifications of candidtions and regardless of sex.

National Insurance Bill.

A meeting of medical men of Lancashire and Cheshire was held on Saturday, Nov. 18th, in Manchester. The meeting had been called—

in view of the facts that the Government has entirely failed to satisfy the medical profession in the scheme of medical benefits proposed in the National Insurance Bill; that it has not met the requirements of the British Medical Association; and, further, that Members of Parliament and the public are in ignorance of the universal dissatisfaction existing in the profession, and its inability to work under the Bill as at present drafted.

The demands on which the meeting insisted were the six cardinal points which have already been formulated by the British Medical Association. The meeting was attended by more than a thousand members and was presided over by Mr. G. A. Wright, of Manchester. Dr. E S. Reynolds, of Manchester, proposed the following resolution, which was passed:—

That in the opinion of this meeting the National Insurance Bill as at present framed does not satisfactorily embody the demands of the medical profession, as defined in the "six cardinal points" formulated by the British Medical Association; that the scheme of the Bill in its present form is unworkable and will create a condition of affairs not only detrimental to the medical profession, but also dangerous to the public health—therefore this meeting of the medical profession of Lancashire and Cheshire expresses its determination, in the event of the Bill becoming law in its present form, to unite with the whole of the profession in declaring its inability to undertake the duties which the Bill proposes to assign to it.

Nov. 21st.

WALES.

(FROM OUR OWN CORRESPONDENT.)

Brecknockshire School Medical Inspection.

THE population of the county of Brecknock is approaching 60,000, so that it is not surprising to find the school medical officer, Mr. J. C. Bridge, who is also county medical officer of health, reporting to the local education authority that he finds it impossible single-handed to follow up satisfactorily those children whom he finds on inspection to be defective. Of the children already examined by him, and whose parents have been advised to seek for them medical treatment, only 23 per cent. followed this advice. He has suggested to the authority that the homes of the children in question should be visited by a nurse, who might persuade the parents to have their children medically attended to. He has endeavoured to obtain for this purpose the services of the district nurses, and although in a few instances the district nursing committees have agreed to this course his proposals have not met with much encouragement.

Honorary Degrees—University of Wales.

At the graduation ceremony of the University of Wales, held at Bangor, the honorary degree of LL.D was conferred upon Sir Isambard Owen, Vice-Chancellor of the University of Bristol, who was one of the founders of and for several years senior deputy chancellor of the University of Wales. The honorary degree of D.Sc. was conferred on Dr. W. T. Edwards, the senior medical practitioner in Cardiff, who was largely instrumental in establishing the medical school at Cardiff.

A Milk Depôt for Cardiff.

About four years ago the medical officer of health of Cardiff, Dr. E. Walford, reported to the Cardiff corporation upon the desirability of establishing an infants' milk depôt in the town. He then pointed out that to sell pasteurised or "humanised" milk in a municipal milk depôt without any medical control, as was being done in some English towns, seemed to be a waste of money, for there appeared to be no means of knowing whether the results were good or bad He urged, however, that in the first instance there should be established an infant consultation, following the example of similar institutions in France. This suggestion was adopted by the corporation, and an infant consultation was started which has since been doing excellent work under the supervision of Dr. Elizabeth Elder, who has been assisted by a staff of lady health visitors. Within the past few months the question of providing a municipal milk-supply for all persons, and not only for infants, has been under the consideration of the health committee of the corporation, and Dr. E. Walford was instructed to report as to the practicability of such a scheme. His report has recently been issued, and in it, after describing the Rochester (New York) municipal milk-supply and the Danish method of coöperation among dairy-farmers, he pointed out that although the supply of milk on a large scale to all classes of the community under conditions similar to those in force in Denmark was a most desirable end to attain, it was a scheme which properly belonged to private enterprise, and at present, at any rate, seemed to be beyond the legitimate scope of municipal sanitary administration. He asserted, moreover, that no legal powers existed authorising municipalities to carry on the business of milk purveyors to the inhabitants of the district under their control. He strongly urged, however, that a milk depôt should be started in connexion with the infant consultation, so that there might be complete supervision of every detail in the supply of milk from the time it left the cow until it reached the consumer.

Nov. 20th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University Court.

THE Edinburgh University Court met on Nov. 13th. After the adoption of a commemorative minute with reference to the late Dr. Joseph Bell, and recording its appreciation of the services rendered by him to the University, the Court again considered the question of inclusive fees but no decision has been made public. Various applications for recognition as lecturers were granted, including those of Dr. W. Ford Robertson, Edinburgh, as a lecturer on the Pathology of the Brain and Nervous System and Bacteriology in its Relation to Mental Diseases; and of Miss Winifred Muirhead, L.R.C.P. & S. Edin., on Bacteriology in its Relation to Mental Diseases. Both these courses are to qualify for the recently established Diploma in Psychiatry.

Royal Victoria Hospital for Consumption, Edinburgh.

The annual report of the Royal Victoria Hospital for Consumption contains an interesting account of the progress of the Edinburgh anti-tuberculosis scheme. With the original Victoria Dispensary as a centre, the committee of management has a network of agencies which appear likely rapidly to acquire a complete supervision of the tuberculosis existing in the city. At the dispensary are seen such patients as are suitable cases for treatment at home. There also is carried out the "march past" of members of households in which cases of tuberculosis have occurred, and by this means early cases are at once detected. From the dispensary notification of fresh cases is made to the public health authorities of the city. A close coöperation is now maintained between the dispensary and the public health department, the records of the dispensary being at the service of the medical officer of health of the city, while in return the municipality has granted towards the working expenses of the dispensary an annual sum of £450 From the dispensary cases suitable for sanatorium treatment are drafted to the Royal Victoria Hospital, and advanced cases are sent to the Hospital for Advanced Cases, which is supported by the municipality. A farm colony is maintained for the further treatment of sanatorium patients, and this agency during its first year has fully proved its value. A dental department has now been opened at the Royal Victoria Hospital, at which the teeth of every patient are carefully inspected and treated. The school for tuberculous children within the grounds of the hospital has continued to prove a great success, and without exception every child has done well. A staff of physicians and nurses attached to the dispensary undertakes visiting of the homes of the patients. During the past year 2242 visits were paid by the medical officers, and 5273 by the nurses. With regard to the expenses of the hospital and dipensary, the committee reports a reduction in the cost per patient of £3 5*s.* 7*d.* during the year; but notwithstanding this, the ordinary expenditure exceeded the ordinary income by the sum of £2090. The farm colony, for the maintenance of which a separate fund was instituted, will, it is hoped, soon pay its own expenses.

The Sir John Struthers Lectureship.

The first of the lectures under the Sir John Struthers lectureship was delivered before the Royal College of Surgeons of Edinburgh on Nov. 17th by Professor Arthur Keith, conservator of the Museum of the Royal College of Surgeons of England. Professor Keith took as his subject "Anatomy in Scotland during the Life and Times of Sir John Struthers." The chair was taken by Mr. George A. Berry, the President, and among those present were Principal Sir William Turner; Sir James Russell, Edinburgh; Professor A. Robinson, Edinburgh; Professor Johnson Symington, Belfast; Professor J. Musgrove, St. Andrews; and Professor R. W. Reid, Aberdeen. The lecturer showed that at the time when John Struthers, in 1841, commenced the study of medicine the study of anatomy was still in its infancy. The development of the human embryo was almost unknown, the body was supposed to consist of "textures" and humours, and fossil remains of man were unknown. In the succeeding years the anatomists one by one became followers of Darwin, and gradually there took place a revolution in the world of anatomy—a revolution in which Scotland played her part and in which there had been no more courageous rebel than Sir John Struthers, the founder of that lecture. Until the day of his death in 1899 Sir John Struthers fought continuously for freedom to teach and to carry on research. The problems of anatomy were yielding most rapidly to those who used the experimental method, and the modern anatomist had to study the living as well as the dead body. At the close of the lecture Sir William Turner expressed the thanks of the meeting to Professor Keith.

Scarlet Fever in Aberdeen.

For some time scarlet fever and measles have been epidemic in Aberdeen to an unusual extent. For the last four weeks there have been 257 cases of scarlet fever notified.

Representative to the General Medical Council.

The Aberdeen University Court has appointed Professor J. T. Cash, dean of the medical faculty, to be a representative of the university on the General Medical Council in place of Professor D. W. Finlay.

The Inclusive Fee: Effect in Aberdeen.

The Scottish Universities have agreed to institute the inclusive fee in Arts and Science, but in view of the great difficulties in fixing an inclusive fee for medicine the Universities Courts, at their conference in July, resolved on deferring the establishment of an inclusive fee in Medicine, or Arts and Medicine, or Science and Medicine. The Treasury has refused to permit this, and Aberdeen, in common with the other Universities, has received a letter expressing satisfaction with the progress made in adjusting matters so far as the present year is concerned; but as regards the additional grant to be provided for the University in the forthcoming financial year and later, it trusts that the system which has been accepted with regard to the faculties of Science and Arts will be extended and brought into operation simultaneously with the other—namely, from the beginning of the academic year 1912–13. The Treasury is therefore making next year's grant conditional on the inclusive fee being adopted for all the faculties. In Aberdeen the introduction of the inclusive fee of 30 guineas in Arts and 40 guineas with honours will entail a heavy loss in fees, as students have been accustomed to take a larger number of classes than the bare minimum for the degree, and have paid, or been paid for by the Carnegie trustees, separately for each class. It is estimated that the loss in Aberdeen will be not less than £1000 a year. In St. Andrews and Glasgow the sum of 30 guineas is about the average of the fees usually paid, and these Universities will not suffer as Aberdeen will. On this point being shown to the Treasury, the reply was that the loss could be made good out of the new grant; but the Universities contend that this grant was needed for quite different purposes, and that it is unfair of the Treasury to give a new grant, and then attach conditions which detract from its value.

Aberdeen Medical Men and Contract Medical Practice.

A circular in the following terms has been sent to all members of the Aberdeen branch of the British Medical Association: "At a meeting of the Aberdeen division, held in the Medico-Chirurgical Society's Hall, 29, King-street, on Tuesday, 14th inst, the question of the family medical fund in connexion with Friendly Society lodges was under consideration. The meeting unanimously resolved that the time was ripe to terminate this form of contract medical practice. The following motion was also carried unanimously: 'That the secretary circularise all practitioners within three miles of the city boundary to give their adherence to the following: First, to decline to act as medical officer to a Family Medical Fund in connexion with a Friendly Society. Second, to give a pledge not to compete for a Friendly Society Lodge against a colleague holding the appointment at present.' It may be stated that, so far as can be ascertained, all the medical men holding Friendly Society appointments within the city were present save five. You are requested to return the fly-leaf, signed." The pledges contained in the fly-leaf are as follows: "1. I hereby pledge myself not to act as medical officer to a Family Medical Fund in connexion with a Friendly Society. 2. I hereby pledge myself not to compete for a Friendly Society Lodge against a colleague at present holding the appointment."

Baldovan Institution, Dundee.

Dr. John Macpherson, His Majesty's Commissioner in Lunacy, recently visited Baldovan Institution for the Treatment, Education, and Training of Imbecile Children. He reports that his visit produced a favourable impression, not only of the management, which is thorough and devoted, but of the growing importance and progress of the institution. There were many evidences that the institution was becoming every year better equipped for the important social work for which it was founded. The children were well dressed and nourished, the sick carefully tended, and the instruction and training of those who could benefit by them were assiduous and regular. He said that the enterprise of the directors, the good medical care of the inmates, and the single-hearted devotion of the staff deserved more substantial support and recognition from Dundee than they at present received.

Consumption and Local Authorities.

At a meeting of the Dundee public health committee, held on Nov. 14th, the question of the extension of King's Cross Hospital was under discussion. It was shown that the proposed extension—namely, the erection of a pavilion for advanced cases of phthisis and a pavilion for measles, each containing 40 beds, the erection of a new home for nurses of 40 bedrooms, and the provision of additional servants' accommodation—would cost about £16,000, with a first cost of furnishing of £1600, and a cost of maintenance and staffing of £3043. Dr. C. Templeman, the medical officer of health, advised the postponing of the whole question of providing for phthisis meantime. He said that he was of opinion that in a very short time the Local Government Board would throw the responsibility of dealing with phthisis entirely upon local authorities, which he thought might mean a more serious burden upon local authorities than any of them imagined. In the course of further discussion it was stated that by leaving out the phthisis pavilion the primary cost would be reduced by £6000 and the cost of maintenance by £1500. This it was agreed to do. The Order for England issued by the Local Government Board on Nov. 16th making notification of pulmonary tuberculosis compulsory and giving certain powers, such as to supply medical assistance, facilities, and such articles as may be necessary, with a view to preventing infection or removing predisposing conditions, and of appointing additional officers, fulfils Dr. Templeman's prediction. A like Order for Scotland may follow at any time.

Nov. 21st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Medical Profession and the Insurance Bill for Ireland.[1]

THE extraordinarily uncertain and topsy-turvy condition of the National Insurance Bill is well illustrated in the wonderful changes that have taken place in the method of its application to Ireland. At first, when the Bill was introduced, medical benefits applied to that country; then the

[1] On Nov. 22nd we received the following telegram from our local correspondent: "On Nov. 21st the Conjoint Committee of the British Medical Association and the Irish Medical Association passed a resolution in Dublin approving the restoration of medical benefits for Ireland, and on behalf of the profession in Ireland accepting the measure under the same conditions as shall be acceptable in Great Britain."

Chancellor, on Nov. 14th, withdrew them; later, when Mr. Lloyd George and the Irish Members had been made acquainted with the views of the industrial classes who had sent over a deputation to London, the Chancellor said: "If there was a feeling that medical benefit for Ireland should be incorporated the Government would not resist. The question was what bargain could be made with the doctors. It was a question of bargain with the doctors." So far as Ireland is concerned, the following alterations have been made in the Bill:—

1. Separate commissioners with a distinct Irish fund and administration for Ireland.

2. The joint contribution of employer and worker in Ireland will be 5½*d.* instead of 7*d.* in England.

3. The State contribution in Ireland will be 2*d.*, as in England, thus giving in Ireland a larger proportion according to payments. The saving of 1½*d.* is divided as equitably as possible between the employer and the worker.

4. A reduction of 2*d.* per week can be obtained by those who agree to maintain during six weeks' illness their indoor servants and agricultural labourers.

5. Where the wages are under 9*s.* per week there will be no contribution from the worker, who under the Bill as originally introduced would have had to pay 1*d.* a week. This penny is to be paid by the State as an additional contribution.

6. For women the charge will be 1*d.* per week less than for men, in all cases, and there will be the same State contribution.

7. Medical benefits are excluded.

8. The provision that parents must insure their children who are working for them and are not in receipt of wages has been abolished both for town and country.

9. Provision is made for the exemption of home workers when the work is done at the leisure time of the workers and is not their main means of support.

10. Farmers who emigrate to Great Britain as labourers are excluded.

11. The limitation, as originally drafted in the Bill, giving the minimum membership for a society to qualify as an "approved society," has been eliminated.

12. The constitution of Health Committees has been popularised and adapted to Irish conditions.

13. Maternity benefit has been increased, so that sickness benefit may be paid in addition to the 30*s.* mentioned in the original Bill.

The Nationalist Members base their main objection to medical benefit on the feeling that exists in Ireland whilst the present dispensary service exists, although Mr. Birrell said he was sorry medical benefit had been excluded in favour of the retention of the dispensary system. It is right to recollect that in Ireland out of 2724 medical men there are only 810 dispensary officers. The Nationalist Members say the creation of a second service to administer medical benefit would stand in the way of Poor-law reform, while most people feel that the administration of the Insurance Bill by the dispensary system will only intensify the Poor-law methods. Further, in their printed statement the Nationalist Members say the medical benefit, as it exists in England, is only for the insured persons, which would leave in Ireland the wives and children still dependent on the dispensary service, and they add: "Should the fund permit it, medical benefit for the insured and their families can be made an additional benefit," which is entirely contrary to the usual inducement to the medical profession: "True! Your pay for attending the insured man may not be much, but think what you will make by looking after his wife and family."

On Nov. 16th, at a very largely attended meeting of the Ulster Branch of the British Medical Association, held in the Medical Institute, Belfast, Mr. J. G. Cooke, surgeon to the Londonderry Infirmary, being in the chair, a long and interesting discussion took place on the Insurance Bill. Mr. R. J. Johnstone, Dr. J. S. Darling, and Mr. William Burns, who had been members of a deputation that had interviewed the Chancellor of the Exchequer and the Irish Members of Parliament in London, gave an account of what had occurred. It being known that negotiations had been again reopened in reference to the inclusion of medical benefits in Ireland, it was moved by Dr. Darling (Lurgan), and seconded by Dr. E. C. Thompson (surgeon to the Omagh County Infirmary), that the members were willing to act on the same lines in Ireland as their medical brethren in England, a resolution to which effect was passed unanimously.

The urgent recommendation of the Conjoint Committee of the Irish Medical Association and the British Medical Association for the inclusion of medical benefits was considered by the Dublin Division of the British Medical Association at a meeting on Nov. 20th. There was a hot debate on the subject, but ultimately a resolution was carried approving of the inclusion of medical benefits. The voting on the question seemed to show that the dispensary medical officers wish for medical benefits, while other general practitioners are opposed to them. The dispensary officers looked to the medical benefits of the Bill to relieve them of much of their Poor-law work, while if the Bill becomes law without medical benefits being included they fear that a large number of insured persons will seek Poor-law relief, not so much for purposes of treatment as to obtain the necessary certificates of sickness. On the other hand, some general practitioners fear that they are likely to be deprived of much of their private practice and to get very little in return.

At a meeting of the Belfast Division of the British Medical Association, held on Nov. 20th in the Medical Institute, Belfast, the various recommendations of the Council of the British Medical Association were passed with a few modifications, and their delegate, Dr. H. Hanna, was instructed to support them at the London meeting on Nov. 23rd. Among the recommendations were those affirming the necessity of the six well-known points put forward by the medical profession, and another asking that medical benefits should be re-inserted in the Irish part of the Bill.

Dental Hospital of Ireland.

At the annual meeting of the Dental Hospital, held last week, it was stated that the operations during the year numbered 48,370, and that much of the work had been done free. There was still an outstanding debt of £1041 4*s.* 8*d.*, although the income for the year had exceeded the expenditure by £90. There had been 48 students on the roll, of whom 11 had secured diplomas.

Eugenics in Belfast.

At the opening meeting of the Belfast Natural History and Philosophical Society, Major Leonard Darwin gave an address on "The New Science: Eugenics or Race Hygiene." Professor J. A. Lindsay presided, and at the conclusion of the lecture a vote of thanks, proposed by Mr. J. R. Fisher (editor of the *Northern Whig*) and seconded by Professor Greig-Wilson, was accorded to Major Darwin. At a meeting on Nov. 15th it was decided to form in Belfast a branch of the Eugenics Education Society.

The Ulster Medical Society.

The annual dinner of the Ulster Medical Society was held in the Medical Institute, Belfast, on Thursday, Nov. 16th, the President, Dr. H. L. McKisack, occupying the chair. There was a very large attendance. The usual loyal toasts were warmly received. Professor W. St. C. Symmers then proposed the health of the guests, to which the new Recorder, his honour Judge J. W. Craig, K.C., and Mr. G. Clark, D.L., replied. The health of the President, proposed by Dr. W. L. Storey, was cordially received, and Dr. McKisack responded. The reunion was a very successful one.

Belfast Guardians and Consumption.

At a meeting of a special committee appointed by the Belfast board of guardians, held recently, to consider the question of sanatorium treatment, after a long discussion it was agreed to recommend—(1) That for the purpose of preserving thorough classification in the Abbey Sanatorium, which it is admitted cannot be completely carried out with the existing buildings, a hospital or pavilion to accommodate from 65 to 70 patients be erected on the lower side of the Administrative House, adjacent to the pavilions for female patients, and that a suitable fence be also erected; (2) that steps be taken immediately for the appointment of an additional visiting medical officer and an additional resident medical officer, Dr. Robert Hall to remain as senior medical officer, to take charge of the administration and to allocate the work of the medical staff.

Typhoid Fever in Omagh Asylum.

At present there are about 66 typhoid fever patients under treatment in the hospitals connected with the Tyrone and Fermanagh Asylum at Omagh, which, with the three patients being nursed in the hospital and the number who have died, make about 80 cases since the commencement of the outbreak. No new cases have arisen within the past few days, and it is likely that the most critical part of the epidemic is over.

Nov. 21st.

THE German Colonial Ministry is sending Dr. O. Glantz, assistant in the Berlin University Ophthalmic Clinic, to Samoa, to study and report upon the infectious eye disease which is prevalent there.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Danger of Drop Bottles.

M. Pron has pointed out to the Therapeutical Society a serious defect, which does not receive sufficient consideration, in the use of drop-bottles, a defect which might have serious consequences. When the bottles are used for watery or alcoholic liquids they give drops much too large, with the result that, for instance, a patient ordered to take 0·70 gramme of an alcoholic tincture actually absorbs, when dropped from a bottle, an entire gramme.

Contagious Diseases.

The French and German Governments have arranged for an immediate exchange of notification between the proper authorities of the frontier jurisdictions of the two countries in the event of the outbreak of contagious diseases affecting either man or beast. The arrangement will come into force on Dec. 11th.

The Right to Publish Reports of Medical Proceedings.

This question of law has been raised at the general assembly of the Association of French Medical Journalists. The association's legal adviser has stated that a journal has no right to publish a clinical lecture, which is presumably his property, without the authority of the lecturer.

A Medical Sculptor.

Dr. Paul Richter, in addition to his acknowledged medical status, is an engraver of marked talent and a sculptor of repute. In this capacity he has added to his title as a member of the Academy of Medicine that of member of the Academy of Fine Arts. He has just completed two medallions designed to commemorate two scientific personages. The first was brought about as the result of an international subscription, and shows on the obverse a bust of Sir Patrick Manson, having on the reverse an allegorical design portraying the labours of the illustrious scientist in tropical diseases. The second, which was engraved for the occasion of the bi-centenary of the Veterinary School of Lyons, commemorates the life-work and discoveries of Professor Arloing, of Lyons. It bears on the obverse the profile of the scientist and on the reverse a tableau of bovine antituberculosis vaccination.

The Evolution of Tuberculosis during Pregnancy.

At a meeting of the Obstetrical Society of France this important question has been taken up and studied afresh. For many years it has rightly occupied the attention of the medical world. It had already been considered at the congress at Rome in 1902, and since then medical men of all countries have been engaged upon it. The occasion for the interruption of pregnancy has especially been worked at up to now; abroad opinion was clearly in favour of intervention, while in France a more conservative view has prevailed. The recent researches of Schmorl on placental tuberculosis have aroused fresh interest in the question. It has been demonstrated that pregnancy may light up a latent tuberculosis and that this aggravation may become manifest only after delivery. It is due to the lessened resistance, by the absence or diminution of the antibodies in the pregnant woman and after confinement. Although placental tuberculosis is hardly admitted as a fact in France, M. Bar and his pupils in their researches have demonstrated the presence of placental tuberculosis on four occasions. In regard to treatment, also, accoucheurs are divided into abstentionists and interventionists. But there is no certain means of distinguishing cases in which medical treatment alone gives satisfactory results and those in which early intervention is necessary; the tuberculin test is interesting, for it seems to be the case that in every woman at the beginning of pregnancy a violent reaction to tuberculin, even if the pulmonary lesions appear to be extending, indicates a relatively good prognosis, while the negative phase, coinciding with even slight lesions, indicates a very serious prognosis. It is difficult to know whether it is better to induce abortion or to resort to surgical operation. If the placental tuberculosis is very marked hysterectomy seems indicated. If the aggravation is due to inhibition of the antibodies abortion appears sufficient.

Disturbances at the Faculty of Medicine.

The reopening of the course of M. Nicolas, professor of anatomy for first and second year students, has been the signal for disorder. It was impossible for M. Nicolas to make himself heard. Appeals written on the blackboard for silence were in vain. About 500 students were gathered in the amphitheatre. After disorderly behaviour for three-quarters of an hour, they began to throw coppers and paper pellets into the well. At 5 o'clock M. Nicolas was compelled to retire. This is the third year in which these disturbances have occurred. It is probable that they will result in the suppression of the course for the entire year.

The Maison du Médecine.

I chronicled at the time of its foundation, two years ago, the happy inspiration that had brought medical men together for the charitable purpose of founding a house of retreat in which, for the smallest possible sum, unfortunate *confrères* could live in honourable comfort. The president of this society, Dr. Courtault, having died a tragic death during a voyage, the council of administration of the House of Rest has elected in his place M. Paul Reyniez, a surgeon to the hospitals, professor *agrégé*, and member of the Academy of Medicine.

Death of Dr. Albert Louis.

Another victim to professional duty, Dr. Albert Louis, surgeon-major to the expeditionary corps in Morocco, succumbed on Oct. 8th in the field hospital at Casablanca from typhoid fever contracted at the bedside of the numerous typhoid patients whom he devotedly tended at the field hospital at Meknes.

Nov. 21st.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Opening of the New Clinics.

ON Nov. 4th the three new clinics were formally opened by representatives of the Government, the University, and the municipality in the presence of a great number of invited guests and other persons interested in the ceremony. On the conclusion of this part of the proceedings the visitors had an opportunity of examining the various details of the new buildings, in the course of which inspection many interesting particulars were brought to their notice.

For instance, in Professor von Noorden's clinic, which has 100 beds, special attention will be paid to the study of disorders of metabolism, and for this purpose a separate kitchen has been provided, in which the kind of food and the proper quantity of it necessary for the individual treatment of such patients will be prepared. This kitchen is at present the only one of its kind in a continental general hospital. Not only students, but also practitioners and nurses, will thereby be enabled to make themselves acquainted with the important dietetic management of patients suffering from diabetes, gout, obesity, and other abnormalities of nutrition, as well as with the scientific principles on which the treatment is founded. Another remarkable innovation in the clinic is the department for physical therapeutics, containing appliances for gymnastics, medico-mechanical exercises, electro-therapeutics, hydro-therapeutics, electrical baths, and various other baths in which sand, mud, and brine are made use of. Chemistry naturally plays an important part in this clinic, and a splendidly equipped large laboratory is provided, as well as a fine library, the nucleus of which consists of the library of the celebrated Professor Nothnagel, who bequeathed it to his clinic. The latest improvements have been introduced in the building of the institute. The lecture room has excellent acoustic properties, ample means of exit for the students, and convenient arrangements both for darkening the hall and for demonstrations with optical apparatus; on the roof there is a garden, part of which is occupied by hutches for the animals used in the experimental laboratories, one such laboratory being allotted to each of the new clinics. The staff of the clinic, to which a large out-patient department for nervous diseases is attached, consists of 2 professors (Professor von Noorden and Professor von Frankl-Hochwart), 8 assistants, 12 house physicians, and 37 nurses.

A noteworthy improvement has been introduced in the Clinic for Children, at the head of which is Professor

von Pirquet. The idea has been to prevent as far as possible a transmission of infectious diseases in the out-patient department, and for this purpose the following system has been adopted. At the entrance of the clinic an experienced matron sees the child, and if there are manifestations of infectious disease the patient is sent at once, by a special exit, to the examining medical officer, while if there is any suspicion of such disease the patient is sent to the "observation station." This consists of an examination hall, divided up into (1) several small compartments, each of which is disinfected after each patient, and (2) the observation cells. When the child has been seen by a medical man in the examination compartment, if the case be infectious the child is sent through a special exit into the pavilion for scarlet fever or diphtheria, or whatever the disease may be. If the diagnosis is uncertain the child becomes an inmate of the observation cells. There are 12 of these, six on each side of a long corridor—the so-called "clean corridor"—whilst on the outer side of each series of cells there is another corridor, the "infected corridor," through which the cells may be entered. The cells are constructed mainly of glass and iron; a cell in the centre is elevated, and is used by the nurse, who in this way can supervise all the cells. By this system the patients are separated from each other, but they can be seen by friends and students from the clean corridor without risk of propagation of disease, and if found infectious or non-infectious are treated accordingly, without themselves running any risk, as would be the case if they should be sent into an infectious ward with an uncertain diagnosis. This clinic has 66 beds, besides 22 beds each in the diphtheria and the scarlet fever pavilion, and one of the chief objects of the clinic will be a thorough instruction of nurses and medical practitioners in the management of infants' diet. There are also several cots—*couvenses*—for infants born prematurely, and the greatest care has been taken to secure efficiency in every detail.

The Throat Clinic, under Professor Chiari, is likewise a modern building accommodating 50 in-patients in spacious lofty wards. Special attention has been paid to the fitting up of the out-patient department in this clinic. In the darkened hall 20 patients can be examined by the medical men and students at a time, and the sterilisation of instruments, mirrors, speculums, and probes is effected by boiling water, into which wire-gauze cups filled with the instruments are dipped. Bronchoscopic work is possible on a large scale, as well as rhinological and laryngological operations, both minor and major, such work being performed in special operating theatres. There are also a fine library and excellent laboratory facilities. The large number of patients will make the work most instructive, and there is no doubt that this clinic is at present the largest and finest of its kind.

As a visitor justly remarked, the hospital patients, mostly in poor circumstances, are now better cared for than patients of the wealthier classes; for the best medical advice and the best therapeutical appliances of every kind, in excellent wards and in the most favourable hygienic conditions, can be had free of charge by the poor in these new clinics. All this, however, has to be paid for, and it is not surprising that each patient costs the hospital at least 6*s*. per day, whilst an operation with an anæsthetic costs anything between 15*s*. and 40*s*. net expenditure. The expenses of carrying on the institutes are in fact so high that special collections are now being made for their benefit.

Nov. 20th.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

New York City Death-rate.

WITH the month ended Oct. 31st the death-rate was the lowest for any month in the history of New York city. According to the Health Commissioner, Dr. Lederle, the decrease took place in practically all diseases, the greatest decrease, however, occurring in diseases of children, in which the death-rate fell 50 per cent. The mortality-rates from infectious diseases have also decreased for the entire city, and for the first time for years the death-rate from heart disease and Bright's disease has been considerably below the average.

Higher Entrance Requirements for Medicine at Cornell University.

Cornell University Medical College opened this year with a smaller enrolment of students than for years past. This is attributed to the new requirement of a bachelor's degree in science or arts, with somewhat longer than one year's work in physics, chemistry, and biology.

The New York County Medical Society.

This society held its 106th annual meeting on Oct. 24th, and adopted a new constitution to replace that drawn up in 1806, when it had 371 members; it has now 2400 members, and feels the need of adapting its rules to the exigencies of modern practice. A lively debate was held over the proposal to move the historic New York Hospital to Sixty-fourth-street and Tenth-avenue, a district already fairly well served, while the northern part of the city is almost destitute of ambulance service. The new officers are: President, Dr. Charles G. Kerley; Vice-Presidents, Dr. Brooks H. Wells and Dr. T. Passmore Berens; secretary, Dr. John Vandoren Young; treasurer, Dr. Charles H. Richardson.

Food Law Violations.

A New York grocer made his fourth appearance before a judge the other day, accused this time of selling ice-cream which was sour, 26 per cent. below the required fat content, and liberally adulterated with gelatin. He blandly explained to the judge that he was ready as usual to pay a fine, and was considerably taken aback when he found himself sentenced to 30 days' imprisonment. Fines ranging from £2 to £20 were then imposed on first offenders for selling decayed fish, skimmed and watered milk, rancid butter, and eggs of dubious age. Imprisonment seems to be the only efficient remedy for food law violations; the recently imported immigrant looks upon fines as a sort of licence fee and pays them cheerfully.

Motor-car Accidents in Massachusetts.

The Massachusetts Highway Commission has reported that there were 1357 motor-car accidents in the State during ten months of the present year, in which 1100 persons were injured and nearly 100 were killed. In 1910 there were 77 deaths and 963 injured caused by motor vehicles in the same State.

Eugenics in Michigan.

The State Board of Health of Michigan has decided to employ an expert in eugenics to investigate the condition and extent of feeble-mindedness in Michigan.

Anti-typhoid Vaccination in the United States.

Throughout the United States the use of anti-typhoid vaccination is rapidly increasing. It is now compulsory in the army. Several States also propose to employ this preventive measure.

Investigation of Pellagra.

The Department of Tropical Medicine of the New York Post-Graduate Medical School is making plans for the investigation of pellagra in the Southern States during the coming spring.

Do American Lifts Shorten Life?

Professor Franz Bergmann, of Berlin, has informed a newspaper reporter of Los Angeles, California, that the lifts in American 20-storey buildings shorten life by the successive shocks they administer to passengers in their abrupt method of starting on, which frequently causes vertigo in a foreigner. Elevator boys, however, do not seem to suffer, and men accustomed to the speedy lifts, which are an absolute necessity, never complain. Professor Bergmann also asserts that the tight shoes of American women are causing the disappearance of the little toe. We are not taking our learned visitor very seriously.

Diphtheria in Indianapolis.

Diphtheria is reported to be alarmingly prevalent in Indianapolis. Proprietors of places of amusement, especially of moving picture shows, have been advised not to admit children, and parents have been requested by the health authorities to keep at home all children under 16 years of age.

Death of Dr. Henry Clay Dalton.

Dr. Henry Clay Dalton died recently from acute appendicitis at St. Louis, where he had practised since 1885. During

his tenure of office as superintendent and surgeon in charge of the St. Louis City Hospital he gained a high reputation as an abdominal surgeon. He is said to have been the first surgeon to operate successfully on stab wound of the liver.

Nov. 11th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Accelerated Promotion in the Indian Medical Service.

AT the present moment, when it is generally accepted that the War Office has decided to abandon the system of acceleration of promotion to the rank of major, which was introduced with the first session of the Royal Army Medical Corps in 1903, it is interesting to note that the Indian Government has notified that rules for accelerated promotion will be given retrospective effect and made applicable to (1) existing majors of the Indian Medical Service who have not completed 16 years' service and have not been able to obtain study leave to qualify for accelerated promotion; and (2) majors of the Indian Medical Service who entered the service after Jan. 30th, 1893, and had already taken study leave and qualified for accelerated promotion in the rank of major before completing 16 years' service.

Lahore Medical College.

It is understood that Major J. Stephenson, I.M.S., is likely to be employed as Professor of Biology in the Government College, Lahore, for a further period of five years from Oct. 1st.

The Dufferin Fund.

Not the least important of the reforms being introduced by Surgeon-General C. P. Lukis, Director-General of the Indian Medical Service, is a proposal to establish a graded service of medical women for the Dufferin Fund and to provide a provident fund for medical women serving under the Fund. The reforms are estimated to cost between three and four lakhs of rupees per annum, and as the funds of the central committee are already fully allotted, the fate of the proposals depends upon the attitude of the Secretary of State and the Government of India. At a meeting of the central committee, under the presidency of Lady Hardinge, on Oct. 7th, it was resolved to lay the scheme forthwith before the Secretary of State through the Government of India. The scheme, in addition to its financial aspects, introduces new disciplinary clauses which are intended to give medical women, of proved fitness, more freedom in their own hospitals in their relations with the local civil surgeons.

The Bedford Scientific Research Scholarships.

The following *communiqué* has just been issued by the private secretary to the Viceroy: "Colonel C. H. Bedford, M.D., I.M.S., lately chemical examiner and bacteriologist, Burma, has munificently decided to bequeath from the date of the death of himself or his wife, whoever may be the survivor, a sum of several thousand pounds sufficient to afford ample endowment for two or more scholarships, and to provide necessary working funds in connexion therewith, for the prosecution of scientific and technical research in connexion with the development of Indian industries."

Ambulance Work in India.

The annual report of the Indian branch of the St. John Ambulance Association has just been published. It shows the amazing amount of progress which can be achieved in a comparatively short space of time, and reflects especial credit on the honorary secretary who has devoted his leisure for the past three years to the movement. There are now no less than 54 working centres, and a short report from each centre is published showing that all are in working condition. The roll of life members has been materially added to and the financial condition of the branch is sound. A detailed account of the work done under the following headings is given: Military Forces, Volunteers, Railways, Police and Jails, Schools and Colleges, Mercantile Marine, Indian Mines, Imperial Service Troops, and Frontier Militia, whilst a brief account is also given of the vernacular translations of the Association's manuals, the Indian stores depôt, and the annual competitions for some handsome trophies possessed by the branch. One of the most interesting features of the report is the account of ambulance work in feudatory India. Centres have been formed in ten independent states and the following ruling princes are shown as actively interested in the movement—viz., the Maharaja of Mysore, the Maharaja Gaekwar of Baroda, the Maharaja of Jaipur, the Maharaja Scindia of Gwalior, the Maharaja of Indore, the Begum of Bhopal, and the Rajahs of Faridkot and Nagod. The work appears after many years' effort to have at last taken firm root in India, and the Government of India should feel especially grateful to the medical officers of both services who are devoting so much of their scanty leisure to promote this great humanitarian propaganda amongst the natives.

Sanitation in India.

There is growing up amongst educated Indians a steady demand for better sanitary conditions, and everywhere one finds them demanding that Government should give the subject more attention. In the legislative assemblies many speeches have been made on the subject, and in his presidential address delivered at the meeting on Sept. 26th of the Third Punjab Hindu Conference at Amritsar, Rai Bahadur Lal Chand made some very pertinent observations regarding the comparative urgency of the claims on public funds of sanitation and free primary education. The speaker maintained that sanitation was not of less importance than free education. He went on to say: "People must live healthy, be strong and fit in physique before they can take advantage of elementary education. What is the use of literate boys and girls whose health is ruined by malaria and phthisis and various other diseases due to insanitary conditions? In my opinion the first question is to live, and live long and healthy lives. Where is the use of insisting on taxation for free education when the majority of children die before they are a year old?" The position taken by the Rai Bahadur is that if additional taxation were to be levied the proceeds should be spent in promoting sanitation rather than in organising a scheme for free and compulsory education. This is a view with which most sensible persons find themselves in agreement. In this relation we find that most of the provincial governments are showing activity on the subject, the most recent move being that of the Madras Government, which has just passed orders on a scheme for investigating the causes of malaria. At Ennore, a village on the sea coast a few miles away from Madras, in which a number of European residents possess bungalows and which is a popular week-end resort, measures are also to be taken for the discovery and destruction of mosquito-breeding places. The Government say that the correspondence that they have had with various medical authorities lays particular stress upon the danger to the city of Madras which arises from the conditions now prevailing at Ennore, and emphasises the need for carrying out preventive work in a thoroughly efficient manner and under the supervision of an officer possessed of special qualifications and superior status. His Excellency the Governor in Council is in general accord with this view of the position and agrees with the officers consulted as to the necessity for initiating a definite campaign of preventive work without further loss of time. The scheme approved falls under two main heads—viz.: (1) a detailed investigation of the cause of the prevalence of malaria in Ennore and the vicinity, and (2) the location and destruction of breeding places of anopheline mosquitoes in that neighbourhood. Major T. S. Ross, I.M.S., is placed in charge of the work.

Oct. 24th.

DONATIONS AND BEQUESTS.—The Governors of Westminster Hospital have applied the sum of £2000 out of the amount paid for seats to view the Coronation procession to form an endowment in perpetuity of two beds, to be named respectively "King George's Bed" and "Queen Mary's Bed," in commemoration of their Majesties' Coronation on June 22nd, 1911.—The late Miss Bell, of South Marston, Wilts, has bequeathed £1000 to the funds of the Victoria Hospital, Swindon.—Mr. Harry Speakman Webb, M.R.C.S. Eng., formerly of Welwyn, Herts, who died at Winchester on July 2nd in his 84th year, has bequeathed a legacy of £500 to the Essex and Hertfordshire Benevolent Medical Society.—The Royal Dental Hospital, Leicester-square, has received a donation of £100 and a new yearly subscription of £50 from Mr. James Buchanan, a donation of £52 10*s.* from N. M. D., and £10 10*s.* each from the Skinners' Company and Messrs. Drummond.

Medical News.

UNIVERSITY OF LONDON.—At examinations held in October the following candidates were successful:—

THIRD (M.B., B.S.) EXAMINATION FOR MEDICAL DEGREES.

Honours.—*George Gushue-Taylor, London Hospital; *John Cecil Jefferson, Victoria University of Manchester; †Oswald Robert Kelly, Westminster Hospital; *‡Henry Linnington Martyn (University medal), King's College Hospital; *Sidney Bertram Radley, Victoria University of Manchester; *Edward Gustave Schlesinger, B.Sc., Guy's Hospital; and *Theodore Henry Whittington, King's College Hospital.

* Distinguished in Medicine. † Distinguished in Forensic Medicine. ‡ Distinguished in Surgery.

Pass.—Gilbert Alan Blake, Guy's Hospital; Gertrude Brooks, London (Royal Free Hospital) School of Medicine for Women; Monamy Aston Cornwall Buckell, University College Hospital; Ronald Herbert Candy, London Hospital; Alfred Bernard Clark, University of Sheffield and University College Hospital; Frank Cook, B.Sc., Guy's Hospital; Thomas Peters Edwards, St. Bartholomew's Hospital; Ralph Franklin Eminson, Charing Cross Hospital; Cyril George Galpin, St. Mary's Hospital; Geoffrey Hadfield, St. Bartholomew's Hospital; Herbert Leslie Hopkins, Guy's Hospital; Arthur Webb Jones, St. Thomas's Hospital; David William Jones, London Hospital; Evan Hugh Jones, St. Thomas's Hospital; Thomas Lewis Jones, Guy's Hospital; Ernest Charles Lindsay, London Hospital; George William Lloyd, St. Bartholomew's Hospital; Joseph Howell Lloyd, London Hospital; Mary Francis Lucas, London (Royal Free Hospital) School of Medicine for Women; John Tiley Montgomery McDougall, Guy's Hospital; Melville Douglas Mackenzie, St. Bartholomew's Hospital; Geoffrey Marshall, Guy's Hospital; James Menzies, St. Mary's Hospital; Douglas Ashley Mitchell, Guy's Hospital; Clement Treves Neve, St. Bartholomew's Hospital; Ambrose Wilfred Owen, St. Mary's Hospital and University College, Cardiff; Alfred Alexander Webster Petrie, University of Edinburgh; Reginald Edward Porter, London Hospital; Walter Woodall Pratt, University of Bristol; Noel Ravenchil Rawson, London Hospital; Maude Margaret Richards, London (Royal Free Hospital) School of Medicine for Women; Charles Frank Schuler, St. Thomas's Hospital; David Scurlock, St. Mary's Hospital; Edward Bertram Smith, St. Bartholomew's Hospital; Albert Joseph Tonkinson, London Hospital; Edith Eleanor Tucker, London (Royal Free Hospital) School of Medicine for Women; George Edgar Septimus Ward, Middlesex Hospital; Harvey Henry Vincent Welch, St. Thomas's Hospital; James Cowan Woods, London Hospital; Roger Michael Wright, University of Bristol; and James Montagu Wyatt, St. Thomas's Hospital.

The following candidates have passed in one of the two groups of subjects:—

Group I.—Gilbert Charles Chubb, D.Sc., University College Hospital; Irene Nancy Clough, London (Royal Free Hospital) School of Medicine for Women; Vincent Glendining, Guy's Hospital; Thomas Herbert Holroyd, University of Birmingham; Edward Lewis Hunt, St. George's Hospital; Charles Dones Killpack, Guy's Hospital; Harold Arundel Moody, King's College Hospital; Henry Brice Parker, London Hospital; Bernard Rayne Parmiter, Guy's Hospital; Mary Minnie Patterson, London (Royal Free Hospital) School of Medicine for Women; and Neville Alexander Dyce Sharp, Guy's Hospital.

Group II.—John Wroth Adams, St. Bartholomew's Hospital; Melville Mortimer Adams, Guy's Hospital; Edwin Augustus Attenborough, London Hospital; Joseph Henry Campain, Guy's Hospital; William Chalmers Dale, St. Bartholomew's Hospital; John Lloyd Davies, University College Hospital; John Beatson Dunning, Guy's Hospital; Macormack Charles Farrell Easmon, St. Mary's Hospital; Archibald Ferguson, St. Bartholomew's Hospital; James Maurice Foord, University of Leeds; Norman Frankish Graham, London Hospital; Arthur Sydney Hahn, University of Sheffield; Guy Fleetwood Haycraft, Guy's Hospital; Robert Hamer Hodges, King's College; William Henry Kauntze, Victoria University of Manchester; Andrew Bonar Lindsay, London Hospital; Martin Wentworth Littlewood, St. Thomas's Hospital; Robin Pearse, St. Bartholomew's Hospital; Cecil Joseph Herbert Pearson and Emmanuel Prinski Scott, London Hospital; Reginald Gershom Sparkes and Arthur Hitchings Thomas, St. Mary's Hospital; and Francis Silvanus Williams, University College, Cardiff, and St. Bartholomew's Hospital.

B.S. EXAMINATION (*for Students who Graduated in Medicine in or before May, 1904*).

James Bruce-Bays, M.D., St. Mary's Hospital; and Lewis Cook, Westminster Hospital.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Hathey, Oberarzt of the University Ophthalmic Clinic, has been appointed to act as Professor of Ophthalmology during the vacancy caused by Professor v. Michel's death; Dr. Albrecht, late of Tübingen, Assistant to Professor Killian, has been recognised as *privat-docent* of Otology and Laryngology.—*Clermont:* Dr. Perrin has been appointed to the chair of Natural History in succession to the late Dr. Girod.—*Marburg:* Dr. Hohmeier, of Greifswald, has been appointed Oberarzt of the Surgical Clinic of the University; Dr. Wilhelm Grüter has been recognised as *privat-docent* of Ophthalmology; Dr. Ludwig Kirchheim as *privat-docent* of Medicine.

MIDLAND OPHTHALMOLOGICAL SOCIETY.—On Nov. 14th Mr. D. C. Lloyd Owen presided at a dinner held in Birmingham for the purpose of founding a Midland Ophthalmological Society. About 20 ophthalmic surgeons gathered from Birmingham and other Midland towns and unanimously decided to form the society. Mr. Lloyd Owen was elected president, Mr. H. Eales treasurer, and Mr. J. Jameson Evans and Dr. T. Harrison Butler secretaries. It was decided to confine the membership to ophthalmic surgeons and to hold bi-monthly meetings throughout the year. Members have been enrolled from Birmingham, Leicester, Nottingham, Gloucester, Cheltenham, Walsall, Newcastle, Leamington, and other towns in the Midland area.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Hans Ruge, *privat-docent* of medicine, with the titular rank of professor in the University of Berlin, aged 54. His first post was that of assistant in the Pathological Institute, Heidelberg, under Professor Arnold, and he then migrated to Berlin as assistant in the Second Medical Clinic of the Charité under Professor Gerhardt. He went during the summer to Kudowa, where he was official physician to the baths. For many years he was secretary to the Balneological Society. His contributions to medical literature on pathological matters were numerous. For some considerable period before his death he had been in bad health.—Dr. Hans Steinert, extraordinary professor of medicine in the University of Leipsic, aged 36. He had very recently returned from Davos, where he had been hoping—unsuccessfully as it proved—to regain his health. His published papers dealt principally with subjects connected with diseases of the nervous system.—Dr. Hermann Gareis, assistant in the bacteriological laboratory of the municipality of Munich, from typhus fever contracted in the course of his laboratory work. His age was only 36.—Dr. Philipp Stoehr, professor of anatomy in the University of Würzburg, aged 62. He had been a student under Kölliker and afterwards anatomical assistant in Greifswald under Budge and in Breslau under Haase, returning to Würzburg in 1876 as assistant to his old professor, whom he succeeded in 1897, after having filled the anatomical chair at Zürich for a time. His publications included a well-known text-book of histology, which has been translated into several languages.

NATIONAL DENTAL HOSPITAL.—The annual dinner of the past and present students of the National Dental Hospital and College, Great Portland-street, London, was held on Nov. 17th, in the Empire Rooms of the Trocadéro Restaurant, Sir William Ramsay, K.C.B., occupying the chair. After the usual loyal toasts, the chairman proposed the toast of "The National Dental Hospital and College." He reminded his audience that dentistry was an old profession. Papyrus writings had shown that the use of gold for stopping teeth had been in vogue in ancient times, and the stoppings buried with the patient. Dentistry was clearly a branch of surgery, and therefore had to keep pace with science. He pointed out the importance of good training before practice, and hoped that something effective would be done to protect the dental surgeon from the quack. Mr. Sidney Spokes, the Dean of the school, replied to the toast, and he was enthusiastically received. He reviewed the satisfactory progress that had been made at the hospital during the past year. Reorganisation had taken place all round, and he was glad to be able to report that the appeal for funds had met with a generous response, but they were still open to receive further donations. The school also had shown satisfactory progress. The returns at the examinations were very gratifying to both teacher and student. He emphasised the importance of educating the public to realise that the capable man is the right man. It was deplorable that a man could call himself a dental surgeon on a brass plate and so imply that he was a properly qualified man when he held no qualification at all. Dr. H. L. Eason proposed the toast of "The Past and Present Students," and referred to the good feeling which existed between the dental schools of London and to the evils of unqualified practice. The dental profession, he thought, were hardly treated by the Government. The toast of "The Visitors" was proposed by Mr. Kenneth Goadby (Vice-Dean), to which Mr. Rickman J. Godlee, President of the Royal

College of Surgeons, responded. He remarked upon the importance of an aseptic mouth, and mentioned that an abdominal operation was more satisfactory in the absence of oro-sepsis. During the evening prizes were awarded to the successful students of the session 1910–11, and a musical programme was provided.

A BRISTOL CENTENARIAN.—Mary Emblem died recently in the Bristol Workhouse at the age of 101 years. She had resided in the institution for the past 11 years.

Dr. Gustav Wagner has been appointed Medical Adviser to the Prussian Minister of Public Works in place of the late Dr. Schwechten, general medical officer of ailways.

THE annual festival dinner of the West Ham and Eastern General Hospital will be held at the Hamilton Hall, Liverpool-street Hotel, on Friday, Dec. 8th, at 7.30 P.M., when the chair will be taken by the Right Hon. Sir Edgar Speyer.

PRESENTATION TO A MEDICAL PRACTITIONER.—Mr. Norman Porritt, M.R.C.S. Eng., L.R.C.P. Lond., who has retired after 31 years' practice in Huddersfield, has been presented by his patients with an illuminated address, articles of furniture, a type-writer and desk, and many individual gifts. Mrs. Porritt has received a gold watch and bracelet, and Miss Porritt a watch bracelet.

GLASGOW UNIVERSITY CLUB, LONDON.—This club will dine at the Trocadero Restaurant, Piccadilly-circus, W., on Friday, Dec. 1st, at 7.30 P.M. precisely. The chair will be taken by Principal J. Yule Mackay, of University College, Dundee. Members who intend to be present or to bring guests should give early notice to the honorary secretaries, Mr. W. Craig Henderson and Dr. David S. Roxburgh, at 30, Seymour-street, W.

UNIVERSITY OF OXFORD AND PHARMACOLOGY.—The trustees of the Oxford University Endowment Fund have offered the sum of £1100 for the provision and equipment of a department of pharmacology in the University Museum; the delegates of the Common University Fund will shortly proceed to the election of a University Reader in that subject. Information as to the conditions attaching to the readership may be obtained from the Registrar of the University.—The following have been appointed to examinerships:—Dr. David Hepburn (human anatomy), Dr. W. H. Thompson (physiology), Professor Georges Dreyer (pathology), Mr. F. E. Fremantle (forensic medicine and hygiene), Dr. H. D. Rolleston (medicine), Mr. Charters J. Symonds (surgery), and Dr. F. W. N. Haultain (obstetrics).

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The National Insurance Bill: New Clauses.

ABOUT 20 new clauses were added to the National Insurance Bill on Thursday, Nov. 16th, at the instance of the Chancellor of the Exchequer, and most of them falling under the closure were not even discussed. A separate set of Insurance Commissioners and also a separate Insurance Fund have been given to Wales. One of the new clauses gives to the Insurance Commissioners power to make special orders specifying classes of employment in which a custom prevails to give full remuneration to employees during periods of disease or disablement. In these cases employers who are ready to give six weeks' remuneration may obtain a reduction of a penny per week where the employed contributor is a man, and a halfpenny per week where a woman. The employed contributor obtains a reduction of a penny. It is assumed that hospital nurses may come within the operation of this clause.

The new clause in respect to Local Medical Committees is as follows:—Where a Local Medical Committee has been formed for any county or county borough, and the Insurance Commissioners are satisfied that such committee is representative of the duly qualified medical practitioners resident in the county or county borough, they shall recognise such committee, and where a Local Medical Committee has been so recognised it shall, subject to regulations made by the Insurance Commissioners, be consulted by the Local Health Committee on all general questions affecting the administration of medical benefit, including the arrangements made with medical practitioners giving attendance and treatment to insured persons, and shall perform such other duties, and shall exercise such powers as may be determined by the Insurance Commissioners.

It is anticipated by Ministers that the National Insurance Bill will probably come into operation in July. Mr. LLOYD GEORGE will make an announcement on the matter during the proceedings on the report stage of the Bill.

Committee Concluded.

The Committee stage of the National Insurance Bill was concluded in the House of Commons on Tuesday, Nov. 21st.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 15TH.

Health at Osborne College.

Lord CHARLES BERESFORD asked the Secretary to the Admiralty whether there were cases of scurvy at Osborne College last July; whether a London specialist was sent for to attend the cadets suffering from this affection; whether mysterious complaints of the eyes, known as pink-eye, were constantly occurring; and whether he had official reports showing that there was more illness at Osborne College than at any other public school in England.—Mr. MACNAMARA replied: There were no cases of scurvy at Osborne last July. No London specialist was sent down on this account. There have been no mysterious complaints of the eyes, but, as frequently happens in all schools, mild cases of conjunctivitis have cropped up from time to time. No such official reports as are referred to have been received, and it is not considered that any comparison can usefully be made between the conditions at Osborne, where there are some 400 boys, all of whom are from 12 years and 8 months to 15 years old, and over 200 of whom change every year, and the average public school where the ages vary considerably more and the boys remain for a much longer period.

Mr. HUNT: Is it not well known that Osborne College is unhealthy for boys?—Mr. MACNAMARA: No, Sir.

Sanitary Condition of Harrogate.

Mr. LANE-FOX asked the Chancellor of the Exchequer what was the date of the report on the sanitary administration of Harrogate; whether that report was based on an inspection made fully a year previous to its issue; whether the report referred to a small proportion of the houses in the town; and whether later sanitary reports by the medical officer of health for the borough recorded the remedying of the defects mentioned.—Mr. MCKINNON WOOD (on behalf of Mr. LLOYD GEORGE) replied: The report in question, as my right honourable friend was careful to state on Thursday, is dated Nov. 16th, 1908. It is admitted that the state of affairs to which he called attention existed at the date of its publication in February, 1909. The later reports of the medical officer of health record the remedying of defects, but they also indicate that they existed to a serious extent. I am aware that action has been taken by the council since the report of the Local Government Board inspector, but inquiries that my right honourable friend has since instituted have convinced him that there are still houses in Harrogate unfit for human habitation.

Mr. LANE-FOX: Will the right honourable gentleman point out to the Chancellor of the Exchequer the serious injury such partial statements may do to a growing health resort?—Mr. MCKINNON WOOD: I cannot admit that the statements are partial. I think a good deal of the ratepayers' money is often spent on the more showy portions.

Mr. LANE-FOX: The Chancellor of the Exchequer quoted one report and not the others. Does the right honourable gentleman consider that is a fair way of dealing with the matter?

No reply was given.

Inflammable Flannelette.

Dr. C. ADDISON asked the President of the Board of Trade whether, in view of the Report of the Departmental Committee (Coroners) published in 1910, and the evidence afforded by coroners' inquests held on infants and children that great dangers arise from the use of inflammable kinds of flannelette, the Government was prepared to take steps to prevent the sale of flannelette which did not conform to a standard test, to be prescribed by Government, as to non-inflammability.—Mr. MCKENNA (for Mr. S. BUXTON) said in reply: No steps to prevent or regulate the sale of inflammable flannelette could be taken without legislation for the purpose, and I cannot hold out any immediate hope of the Government undertaking legislation on this subject. The committee considered the question of establishing a standard test, but regarded the suggestion as impracticable.

The Use of Lead Paints.

Mr. GILL asked the Secretary of State for the Home Department whether he had received from the central office of the International Association for Labour Legislation at Basle a petition drawing his attention to a resolution of the association recommending that the use of lead paints and colours should be prohibited for interior work, and that all receptacles containing lead should be required to be clearly marked to that effect, and, if so, what reply had been sent as to what steps he proposed to take.—Mr. MCKENNA answered: I have received through the British section of the association a communication calling my attention to the resolution referred to in the question. The question of the use of lead in paints is now being investigated by two departmental committees, and I do not propose to take any action in the matter pending the receipt of their reports. In any case, further legislation would be necessary before effect could be given to the recommendation of the association that the use of lead should be prohibited for interior work. I have informed the British Section that the recommendations have been noted.

Lead Glaze in Pottery.

Mr. GILL also asked the right honourable gentleman whether he had received from the central office of the International Association for Labour Legislation at Basle a petition drawing his attention to a resolution of the association recommending that the use of lead glaze should be prohibited in the manufacture of china and earthenware fired at a high temperature; that in the manufacture of earthenware fired at a low temperature a list of articles should be drawn up for which no lead should be allowed; that occupiers should be assisted by the Government in making experiments into the use of lead glazes; and, if so, what reply had been sent as to what steps he proposed to

take.—Mr. MCKENNA replied: I have received through the British section of the association a communication calling my attention to the resolution referred to in the question. The question of the use of lead in the manufacture of pottery has recently been the subject of an exhaustive investigation in this country by a departmental committee who did not see their way to recommend restrictions on the use of lead as suggested by the association, but submitted instead proposals for more stringent regulation of the conditions of employment which the Home Office is taking steps to bring into effect. The conclusions of the committee must, I think, in the present state of knowledge on this subject, be accepted as final.

THURSDAY, NOV. 16TH.

Lead-poisoning at Portsmouth.

In reply to Mr. FALLE, Mr. MACNAMARA said that the number of cases of lead-poisoning which had occurred this year in the Gun Wharf shop, Portsmouth, were five, in the dockyard generally five. The numbers of deaths from lead-poisoning were: men employed in the Gun Wharf shop, none; men employed in the dockyard generally, two.

Patent Medicines.

Mr. LYNCH asked the Secretary of State for the Home Department whether he was aware that amongst the patent medicines sold in this country there were some of which the advertisements were merely thin disguises for the suggestion of illegal practices, and that the consequences in a number of cases did not rest with the immediate result sought but produced severe general poisoning, such as lead poisoning; and whether steps would be taken to put a stop to or mitigate these evils.—Mr. MCKENNA replied: I am aware that some of the advertisements suggest illegal practices, but they are in such veiled language, and in many cases the drugs are in fact so innocuous, that it would be impossible to prosecute successfully. This will be a matter for the consideration of the proposed Select Committee.

Mr. LYNCH also asked the right honourable gentleman whether he was in a position to state the general character of the Select Committee he had promised to appoint next session to consider the question of patent medicines, particularly in regard to the terms of reference and the adequate representation thereon of medical opinion.—Mr. MCKENNA answered: I am not in a position yet to make any announcement.

Mr. LYNCH further asked the right honourable gentlemen whether, in view of the fact that many of the patent medicines sold in this country consisted mainly of cheap and innocuous drugs sold at 50 times the real value, he would issue as a Parliamentary Paper a statement of the analyses of the more prominent of such patent medicines, or would take steps to give wider publicity in the general interest to the results of analyses of popular patent medicines obtained by the experts employed by the *British Medical Journal*.—Mr. MCKENNA said in reply: The analyses published by the *British Medical Journal* are no doubt most useful, but I think that the honourable Member will understand that I cannot without independent investigation adopt and publish them officially. The question is one which I must leave to the Select Committee.

Mr. C. BATHURST: Is anything being done to accelerate the appointment of this committee?—Mr. MCKENNA: I have stated already that I propose to appoint the committee next session. It will be appointed early.

Tuberculosis in the Army.

The Marquis of TULLIBARDINE asked the Under Secretary of State for War what percentage the number of men discharged for tuberculosis during the last three years from the regular army at home and abroad bore to the total number of men serving in the army during these three years, taking each year separately—Colonel SERLY replied: The figures are as follows:—

	Average annual strength.	Number of cases discharged.	Per-centage.
1908	223,744	306	0·14
1909	231,316	339	0·15
1910	230,500	285	0·12

MONDAY, NOV. 20TH.

Royal Naval Medical Service.

Mr. BENNETT-GOLDNEY asked the Secretary to the Admiralty whether the Admiralty had received any report from the consultative committee of the Royal Naval Medical Service, and when did they receive it; would he give instructions that this report in its original form should be laid upon the table of the House; had the Admiralty been advised by the consultative committee that the only practical means of obtaining the additional number of medical officers of the high standard necessitated by modern requirements to make up the shortage in the Royal Naval Medical Service is by offering a substantial increase of pay; was this opinion endorsed by the Admiralty; had the Admiralty received any communication from the Army Council upon the subject to the effect that the Army Council would view any decision of the Admiralty to make the career in the Royal Naval Medical Service more attractive by offering a higher scale of pay as antagonistic to the desired flow of candidates to the Royal Army Medical Corps; and, if so, did the Admiralty intend to allow the Royal Naval Medical Service to continue to suffer both in efficiency and numbers in order to enable the Army Council to keep down the pay of members of the Royal Army Medical Corps to its present rate.—Mr. MACNAMARA replied: The Committee on the Naval Medical Service forwarded a report relating to naval medical officers on July 2nd, 1909. My right honourable friend the First Lord is not at all convinced that the public interest would be served by laying this report on the table, which deals fully with medical organisation in time of war, and he hopes the House will not press for it. In reply to the third and fourth parts of the question, the Committee advised that the question of pay was a most important factor to be considered when endeavouring to obtain the requisite number of medical officers of the standard necessary and framed proposals which would substantially increase the emoluments of naval medical officers. The Admiralty endorsed this view and obtained authority for increasing their emoluments. The revised scales of pay and allowances were published in circular letter of August 11th last, a copy of which I am forwarding to the honourable Member. The Army Council agreed that a margin of superiority in rates of pay should be given to the Naval Medical Service, and the scales of pay promulgated in the circular letter quoted provided for this margin in future.

The Medical Examination of Intoxicated Persons.

Mr. BURGOYNE asked the Secretary of State for the Home Department whether he was aware that the Metropolitan Police regulations did not allow of the examination by an independent medical man of a person who had been taken into custody and charged by the police with being found drunk on licensed premises, although the opinion of the police surgeon as to the condition of such person was invariably obtained for the purposes of the police prosecution of such person and the licensee of the premises; and whether, having regard to the subsequent proceedings under the Licensing Acts which usually followed against the licensee of the premises upon which the alleged drunken person was found, he would recommend that in those cases in which application was made to the police by the licensee facilities would be granted for an independent medical examination of the person alleged to be drunk, and, if not, was he prepared to recommend that the person charged should at the same time be informed by the police that if he so desired he might be examined by an independent medical man at his own expense instead of by the police surgeon.—Mr. MCKENNA said in reply: The Metropolitan Police regulations require that the divisional surgeon be at once sent for when a prisoner charged with drunkenness denies that he is drunk, and they further provide that the prisoner's own doctor be sent for if he wishes. There could be no more independent examination than that of the divisional surgeon, who holds his appointment from the Secretary of State and is always a practitioner of good standing.

Collectors or Medical Men.

Mr. JOWETT asked the Secretary to the Treasury whether he was aware of the number of persons employed as collectors for medical men who would be deprived of their employment if the National Insurance Bill was passed; whether he would make it an obligation on the part of Local Health Committees in arranging their financial relations with medical practitioners and surgeons to arrange also to compensate their collectors for loss of employment; and, if not, whether he intended to leave the collectors referred to without means of support for themselves and their families.—Mr. MCKINNON WOOD answered: I am afraid that I cannot undertake on behalf of my right honourable friend to introduce into the Bill this additional complication in the relations between the Local Health Committees and the medical men.

TUESDAY, NOV. 21ST.

Ireland and Medical Benefit.

Mr. WILLIAM O'BRIEN asked the Prime Minister whether, for the convenience of Irish Members, he could say when the proposed restoration of medical benefit to Ireland under Clause 59 of the National Insurance Bill would be under discussion.—Mr. MCKINNON WOOD (Secretary to the Treasury): I will answer this question. As the Chancellor of the Exchequer stated during the discussion on Clause 59 in Committee, his only reason for proposing the omission of medical benefit in Ireland was that he found that Irish opinion, as a whole, desired this alteration. He has received no sufficient evidence that Irish opinion has undergone a change in this respect, and he does not, therefore, as at present advised, propose to ask for the recommittal of the Bill for the object indicated by the honourable Member.

Hospital Staffs in India.

Dr. ADDISON asked the Under Secretary of State for India whether it was the intention of the Government, in connexion with the hospitals and sanatoriums that might be erected in India by public money in connexion with the memorial to King Edward VII., to appoint Indian medical men to serve on the staff of these institutions so far as their experience and training might qualify them for holding such posts.—Mr. MONTAGU replied: I am unable to make a definite statement on the intentions of the Government of India with regard to filling appointments which have not yet been created. With regard to the general question involved, perhaps my honourable friend will wait for my answer to his next question.

Dr. ADDISON asked the honourable gentleman how many Indian medical men held appointments as professors or chief teachers in the teaching hospitals and medical colleges of India; and whether it was the intention of the Government to appoint suitable Indian medical men to such posts so far as opportunity might provide.—Mr. MONTAGU replied: None of the highest posts is at present held by an Indian, but the question of appointing Indians to two such posts is now under consideration. The answer to the second part of the question is in the affirmative. The decision of the Secretary of State in 1909 to allow no further increase in the civil side of the Indian Medical Service was intended to have among its results the appointment of Indian medical men to some professorial appointments of the first rank.

Vaccination in the Isle of Man.

Mr. POINTER asked the Secretary of State for the Home Department whether his attention had been drawn to the fact that since August prosecutions for non-vaccination of children had been taking place nearly every week in the Isle of Man; whether the Island Legislature had considered the question of introducing the exemption clause similar to that operating in England, Wales, and Scotland; and, if not, whether he would bring to the notice of the Governor of the Isle of Man the desirability of legislation which would give Manx objectors to vaccination the same rights as those possessed by their fellow citizens of Great Britain.—Mr. MCKENNA wrote in reply: I understand that there have been several prosecutions lately. The Lieutenant-Governor informs me that the insular Legislature has not considered the question of exemption, and that no representations have ever been made to him as to the desirability of the legislation suggested. If there is any grievance the matter is one for the insular Legislature to consider.

Discharged Lunatics.

Mr. ASTOR asked the Secretary of State for the Home Department whether he would state what number of certified lunatics had, during the last five years, been discharged from asylums and subsequently readmitted.—Mr. MCKENNA furnished the following reply: The Commissioners in Lunacy inform me that they have no means of supplying this information. In Appendix B, Table III., of the annual reports of the Commissioners there will, however, be found the figures of the number of persons admitted to asylums during the year who are known to have been at some previous time in an asylum. Of 23,266 persons admitted during the year 1909 to county and borough asylums 3462 were known to have been in asylums before.

Defective and Epileptic Children.

Mr. GOLDSTONE asked the President of the Board of Education how many local authorities had put the Elementary Education (Defective and Epileptic Children) Act, 1899, into operation; how many children of the various classes were treated by such local authorities during the last statistical year; and what was the estimated number of children not treated through the inaction of those authorities which have not adopted the Act.—Mr. J. A. PEASE (in a written answer) replied: The answer to the first part of the question is 142. With regard to the second part of the question, the number of children on the registers of special schools under the Elementary Education (Defective and Epileptic Children) Act, 1899, in England and Wales on July 31st of this year was 17,333, of whom 12,253 were mentally defective, 4703 physically defective, and 377 epileptic. I have no information with regard to the last part of the question.

WEDNESDAY, NOV. 22ND.

Medical Members of Health Committees.

Mr. CROOKS asked the Secretary to the Treasury whether medical men sitting as members of the Local Health Committees would be allowed to practise under the National Insurance Bill—viz., receive fees for service on attendance upon sick persons.—Mr. MCKINNON WOOD replied: Membership of a Local Health Committee, which is a purely honorary position, will not debar a medical man either from private practice or from attending patients under the insurance scheme.

BOOKS, ETC., RECEIVED.

ARNOLD, EDWARD, London.

My Life Story. By Emily, Shareefa of Wazan. Edited for Mme. de Wazan by S. L. Bensusan, author of "Morocco," &c. With a Preface by R. B. Cunninghame Graham. Price 12*s.* 6*d.* net.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Sidmouth, in the county of Devon; at Exmouth, in the county of Devon; at Cullingworth, in the county of Yorks, West Riding; and at Blaenavon, in the county of Monmouth.

Births, Marriages, and Deaths.

BIRTHS.

COURTNEY.—On Nov. 15th, at Barton, near Ampthill, Bedfordshire, the wife of Harold G. S. Courtney, M.R.C.S., of a daughter.

MARRIAGES.

LEA—BUZZARD.—On Nov. 18th, at St. George's Church, Hanover-square, Charles Edgar Lea, M.D., to Dorothy Cadell, younger daughter of Thomas Buzzard, M.D., F.R.C.P.

RIGDEN—MAY.—On Nov. 15th, at the Church of St. Barnabas, Kensington, Alan Rigden, M.D., to Catherine, daughter of the late Daniel May, of Dudley.

DEATHS.

O'MEARA.—On Nov. 15th, at Carlton House, Holbeach, William Henry O'Meara, L.R.C.P., L.R.C.S. Edin., L.A.H. Dub., Surgeon, R.N. (retired), aged 52 years.

WEBB.—On Nov. 18th, at The Hermitage, Exeter, William Wilfrid Webb, M.D., formerly a Major in the Indian Medical Service Bengal Army, in his 54th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE USE OF DIACHYLON AS AN ABORTIFACIENT.

To the Editor of THE LANCET.

SIR,—In consequence of the increasing prevalence of the habit of taking diachylon as an abortifacient and the evident ignorance of the public as to the poisonous nature of that substance, the Birkenhead and Wirral Association of Pharmacists is attempting to stamp out the habit and to protect those who will not protect themselves, so far as its area of influence is concerned, and at its last meeting unanimously passed the following resolution:—

That in view of diachylon being largely purchased as an abortifacient, this association recommends each of its members to discourage the sale of diachylon, unless he is perfectly satisfied it is going to be used for a legitimate purpose.

May I ask you the favour of inserting the foregoing in your valuable journal? I am, Sir, yours faithfully,

Nov. 16th, 1911. T. STEPHEN JONES, Honorary Secretary.

SOMALILAND HEALTH REPORT.

A REPORT on the Somaliland Protectorate for the year ended March 31st, 1911, has just been received at the Colonial Office. It states, *inter alia*, that no census of the population has ever been taken, but it is estimated that there are about 300,000 Somalis, 200 Indians, 300 Arabs, 20 Europeans and whites, and 100 mixed. The population is probably about stationary, owing to tribal disturbances affecting the general mortality. The country under present conditions is capable of sustaining a limited population only, owing to the limited water-supply and lack of agriculture. The general state of the public health is good. There are comparatively few diseases met with, and these seldom of a virulent type. Malarial diseases and pneumonia are the chief ailments of the winter. A routine examination of persons suffering from malaria is conducted, and any enlargement of the spleen is noted. It may be stated that splenic enlargement is quite uncommon as a rule, just as the usual malarial attack is of a distinctly mild form and occurs only during a very limited period of the year. It is a great deal owing to this fact that the public distribution of quinine, other than at the hospitals, is practically not called for. Occasionally exceptions are made, but the annual consumption of quinine is altogether only some 10 lb. to 12 lb. for the whole coast. At Berbera water is brought to the town and supplied by public fountains. The water is drawn from springs nine miles distant, and is at a temperature of from 95° to 100° F. at the springs. It is conducted through iron pipes, after being partially cooled in depositing tanks. The other towns are supplied from wells at a distance, the water being conveyed in skin bags to the consumers. The water at all the coast towns is more or less brackish, and is on occasion liable to produce severe colic and diarrhœa from mineral impurities and earths.

The Somali has still to learn the proper use of a house for shelter from cold, wind, and dew, and for the protection of his women and children from the ravages of hyænas. He lives chiefly in the open air by day and night. His hut is made of grass, mats, and sticks, occasionally plastered with mud, and is of such slight construction that it can usually be demolished and carried away on a camel at a few hours' notice. The huts of the poorer Somalis are usually about 12 ft. by 8 ft., and the only cleansing, or rather disinfecting, agent they know is the smoke of the smouldering fire which they use for cooking their food. The saving quality of these huts is that they cannot last longer than three or four years.

The climate is chiefly remarkable for its very dry character. Sickness is more prevalent in the winter months, but this is chiefly because during this period of the year caravans from the interior come down to the coast, which is to a great extent abandoned during the extreme heat of summer by the greater part of the population.

A general hospital is situated at each of the three principal coast towns—viz., Berbera, Bulhar, and Zeyla. A disinfecting station, furnished with a Clayton disinfector, exists at Berbera. The withdrawal of the troops from the interior necessitated the closing of the camp hospitals at Burao and Sheik, and has led to the necessary abandonment of the isolation hospital for tuberculous disease and the small-pox hut, which were outside the limits of the town of Berbera. Matting huts were erected as required to meet a small-pox epidemic at each of the three towns. These huts were found to answer the purpose well, owing to the dryness of the climate. The number of admissions to the hospitals was 347; the number of deaths in hospital, 9. These figures are exclusive of 698 cases with 139 deaths from small-pox treated at the small-pox camps. There are three dispensaries, one being attached to each of the three coast hospitals. The attendance of patients during the year totalled 23,151. At Berbera Hospital a room is available for laboratory purposes; this was built last year and steps have now to be taken to supply scientific apparatus and fittings. Ordinary blood examinations and urine testing have been carried out, but apparatus is still needed for proper bacteriological investigation. The medical service of the colony consists of two medical officers assisted by three sub-assistant surgeons, the latter having received their qualifications in India. Native Somalis are employed as hospital servants. There are no special health officers or registered medical practitioners.

HYGIENE IN THE BAKERY.

THERE has recently been started an Electric Machine Bakery at Golders Green by Messrs. R. and T. Pritchard, who deserve a word of praise for applying to practical bread-making sound hygienic principles. The installation affords an interesting contrast to the old, and we are glad to think now obsolete, underground bakery. The objection, also, to the dough coming into contact with the hands of a diligent perspiring "kneader" is entirely overcome by the adoption of a kneading machine worked by the electric current. Further, the flour before being worked into dough is sifted thoroughly from foreign matters by an electric sifter placed immediately above the kneader into which the cleansed flour is fed. Other appliances, as, for example, ovens, automatic weighing and moulding plant, have been installed which also secure the healthy preparation of bread, cakes, and confectionery. Bread made under this clean and sanitary environment needs no commendation from us, who have for years insisted upon sanitary reform being enforced in the baking trade. We are pleased to find such striking evidence of the correct impressions and deductions which our exposures published some years ago have given.

VOICE PRODUCTION.

Mr. Hermann Klein will give an afternoon *causerie* at Bechstein Hall on Monday, Dec. 4th, at 5.30, taking as his subject "The Method of Manuel Garcia and the Stroke of the Glottis." Many medical men are interested in the technique of vocal art, and certain questions of voice production, which have been variously discussed, have a distinct anatomical bearing. We are informed that for the first time on this occasion the famous master's own standpoint will be publicly explained and demonstrated. Mr. Klein was Garcia's pupil and cooperated with his master in a text-book.

THE DOMEN ADHESIVE ELASTIC BANDAGING.

WE have received from the Domen Belts Company, of 456, Strand, W.C., a sample of the Domen adhesive elastic bandaging and have submitted it to tests. It resembles ordinary strapping in that it is adhesive, but it differs from adhesive strapping by its elasticity. It is made from a material something like domette or crêpe, in that it is openly woven, so that it possesses a certain amount of elasticity, which allows it to adapt itself to irregular surfaces. It is porous, so that it allows perspiration to escape. It will stand hot or cold water, and water does not harden it; it is easily removed, although it adheres readily. The adhesive composition is said to contain no lead plaster or rubber or gum; it is certainly very unirritating, so that it may be applied to tender skins. Each bandage is 4 yards in length, and it is made in various widths from ½ inch to 4 inches, the price ranging from 10*d.* to 4*s.* for the 4 yards.

PRINCESS AELFRIDA'S CHARITY.

"Princess Aelfrida's Charity" is the reputed Manor of Old Court, Greenwich, which was originally a grant by Princess Aelfrida, third daughter of King Alfred the Great, of her "inheritance of Lewisham and Greenwich and Woolwich, with meadows, pasture lands, wood, serfs also, and all the above-mentioned inheritance in its entirety" to the Monastery of Blandinium. In two neat little pamphlets with the above title, the Rev. Henry Lansdell, D.D., chaplain of Morden College, Blackheath, records graphically, and often in vigorous terms, the vicissitudes of this charitable gift. The first pamphlet covers the 600 years period, A.D. 918 to 1536, at which time the Manor was diverted from its original purposes to augment the possessions of Henry VIII. The second continues the story from that period until 1699, when the property fell to Sir John Morden, Bart., who gave it as a part of the endowment of his College for "decayed merchants," then building at Blackheath. There are many quaint historical data of interest in these brochures.

R. H.—It is always worth while to try the vaccine treatment of acne with stock vaccine at first, and then if this should fail vaccines prepared from the patient himself may be employed. Our correspondent does not say what form of acne is present; are there only comedones or are there many pustules as well? The mixed vaccine should be used if many pustules are present. The age of the patient is a factor. Diet is important.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for the next few months:—

September–November (Antwerp).—International Exhibition of Alimentation, Brewing, Wines, and Liqueurs.
November (Rome).—Fourth International Congress of Physical Education.
Dec. 1st (The Hague).—International Opium Conference.
,, 4th–9th (Havana, Cuba).—American Public Health Association.
,, 19th–23rd (Moscow).—Third Pan-Russian Therapeutical Congress.

In 1912:—

Jan. 20th–27th (Hong-Kong).—Second Biennial Congress of the Far Eastern Association of Tropical Medicine.
March 23rd–April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.
,, (London).—First Congress of Pure Food and Health Society of Great Britain.
,, (Berlin).—Thirty-third Balneological Congress.
April 1st–7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.
,, 14th–20th (Rome).—Seventh International Congress on Tuberculosis.
,, (Rome).—Seventh International Congress of Dermatology and Syphilology.
,, (Giessen).—Congress on Study of Families, Inheritance, and Race Hygiene.
Spring (London).—Second Optical Convention.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

MONDAY.

ODONTOLOGICAL SECTION (Hon. Secretaries—W. W. James, Stanley Mummery): at 8 P.M.

Casual Communications:
Mr. Frank Coleman: (1) Fistula of the Antrum Closed by Sliding Bone Flaps; (2) An Important Sign in the Diagnosis of Fracture of the Jaw.

Paper:
Mr. A. H. Parrott: Local Anæsthesia with Special Reference to Injection Methods.

TUESDAY.

MEDICAL SECTION (Hon. Secretaries—Sir John F. H. Broadbent, Robert Hutchison): at 5.30 P.M.

Papers:
Dr. F. Craven Moore and Dr. H. E. Allanson: The Influence of Certain Accessory Food-stuffs on Gastric Secretion.
Dr. Parkes Weber: The Association of Hysteria with Malingering, and the Phylogenetic Aspect of Hysteria as Pathological Exaggeration (or Disorder) of Tertiary (Nervous) Sex Characters.

FRIDAY.

LARYNGOLOGICAL SECTION (Hon. Secretaries—W. H. Kelson, Dan McKenzie), at 11, Chandos-street, W.: at 4.30 P.M.

Cases
Will be shown by Dr. William Hill, Dr. Jobson Horne, Dr. Kelson, and others.

SECTION OF ANÆSTHETICS (Hon. Secretaries—Mrs. Dickinson Berry, H. J. Scharlieb): at 8.30 P.M.

Paper:
Dr. Dudley Buxton: Crawford W. Long, the Pioneer of Ether Anæsthesia. The Methods of 1842 and 1911. To be followed by Discussion.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8 P.M., Clinical Meeting. Cases will be exhibited by Dr. de Havilland Hall, Mr. Stebbing, Mr. E. M. Corner, Dr. W. Carr, Mr. D. Fitzwilliams, Mr. W. Low, and others.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, Hammersmith-road, W.

FRIDAY.—8.30 P.M., Dr. S. Taylor: Unrecognised Diphtheria.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. E. Dore: Clinique (Skin). 5.15 P.M., Lecture:—Dr. G. Oliver: On Prœdema and Nascent Œdema, their Detection and Treatment.
TUESDAY.—4 P.M., Dr. J. Taylor: Clinique (Medical). 5.15 P.M., Lecture:—Mr. J. E. Lane: Syphilis d'Emblée.
WEDNESDAY.—4 P.M., Sir A. Pearce Gould, K.C.V.O.: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. W. H. B. Stoddart: The Nature of Hysteria.
THURSDAY.—4 P.M., Mr. E. L. Evans: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. R. H. A. Whitelocke (Oxford): Treatment of Displaced or Injured Semilunar Cartilage of the Knee-joint.
FRIDAY.—4 P.M., Mr. K. Campbell: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. Dr. Simson: Diseases of Women. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. G. Stewart: Treatment of Organic Paralysis.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Pritchard: Clinical Pathology.
WEDNESDAY.—10 A.M., Dr. Simson: Gynæcological Demonstration. Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine. (Lecture IV.).
THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. G. Stewart: Treatment of Hysterical Paralysis.
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Abraham: Cases of Skin Disease.
SATURDAY.—10 A.M., Medical Registrar: Demonstration of Cases in Wards. Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. Bishop Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.
TUESDAY.—2 P.M., Operations. 3.15 P.M., Dr. R. Wells: Medicine. 2.15 P.M., Mr. R. Carling: Surgery. 4.15 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 3.15 P.M., Special Lecture:—Dr. R. Wells: Modern Theories of Heart Disease.
WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.
THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4.30 P.M., Special Lecture:—Mr. Cantlie: Surface Anatomy.
FRIDAY.—2 P.M., Operations. 2.15 P.M., Sir J. Rose Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 2.15 P.M., Special Lecture:—Sir John Bradford: Epilepsy and Epileptiform Fits.
SATURDAY.—10 A.M., Radiography. 11 A.M., Dr. A. Davies: Pathological Demonstration. 2 P.M., Operations. Out-patient Demonstration:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. D. Gillies). 3 P.M., Pathological Demonstration (Dr. Duncan).
TUESDAY.—Clinic; 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld).; Surgical (Mr. Howell Evans); Gynæcological (Dr. A. B. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Lecture:—Mr. Howell Evans: Surgical Conditions of Antenatal Origin.
WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen): Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Mr. W. Steuart); Pathological Demonstration (Dr. Duncan). 5.30 P.M., Eye Operations (Mr. Brooks).
THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. B. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappell). 4.30 P.M., Demonstration:—Dr. T. R. Whipham: Selected Cases of Children's Disease.
FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie); Pathological Demonstration (Dr. Duncan).

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. Inman: Secondary Infections in Pulmonary Tuberculosis.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Mr. D. Armour: Surgery of the Nervous System.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Mr. C. Nourse: Accessory Sinuses.
FRIDAY.—3.30 P.M., Lecture:—Dr. W. Wingrave: Vaccines.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Dr. Sibley: Electrical Treatment in Dermatology.
THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell; Paratuberculides (due to Tuberculous Toxins)—I., Macular; II., Papular; III., Pustular; IV., Pigmentary.

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Mr. E. S. Bishop: Urinary Surgery. (Post-Graduate Clinic.)

OPERATIONS.

METROPOLITAN HOSPITALS.

Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

Two Lectures

ON

UNICELLULA CANCRI;

THE PARASITE OF CANCER.

Delivered before the Royal College of Surgeons of England

BY SIR HENRY BUTLIN, BART., F.R.C.S.,

PAST PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; HUNTERIAN PROFESSOR.

LECTURE II.*—THE PARASITE OF CANCER.

MR. PRESIDENT AND GENTLEMEN,—It will now be convenient to consider how far the theory advanced in the previous lecture will account for the phenomena of malignant disease, as we know them in man and animals. Dr. Charles Powell White, in his lectures on the Pathology of Cancer,[1] says:—

> We can say, then, that cancer is not due to a specific parasite or parasites, but, on the other hand, we can say that cancer cells themselves act as parasites. This view will explain all the phenomena of cancer.

And Dr. James Ewing, in his Cancer Problems,[2] says:—

> The whole basis, objective and theoretical, of the cancer parasite has been traversed again and again, with the uniform conclusion of those who finish the journey that the cancer parasite is the cancer cell.

Dr. White's statement is general and sweeping, but I believe it to be in the main correct, although I am not aware of any detailed analysis on which it rests. So far as time will permit I propose to supply the deficiency.

There are two great phenomena of malignant disease (cancer) which overshadow all the others, and to which most of the other phenomena are subordinate, and on which they are more or less dependent: (1) the tumour and (2) the metastases. The tumour may exist without metastases, and there are reasons for believing that metastases may exist without the presence of a tumour.

1. THE TUMOUR.

The tumour is the primary disease, so far as we know it. Until a very few years ago the presence of a mass was regarded as an essential to the diagnosis of malignant disease. Now we know that the primary—the initial—lesion of cancer (I use the word as synonymous with malignant disease) may exhibit nothing more than a really trivial thickening of a small area of the skin or mucous membrane. From this trivial beginning arise all the various phenomena which go to make up the history of a case of cancer, and from it originate all the misfortunes and sufferings of the individual—the host. For, if this tiny area be examined with the microscope, it will be found to be composed of cancer cells, which are either massed together, as if without law or order, or which may, on the other hand, be arranged with singular and wondrous skill, so that the appearance of the disease may closely simulate that of a natural tissue or organ of the body. (Fig. 6.) There is also provision for the maintenance of the cells, in the form of vessels, and often of scaffolding or framework, in which the cells are arranged. And there are usually numbers of other cells—leucocytes, lymphocytes, granulation cells for the most part—in the outskirts of the tumour. So that the mass is made up of several elements, of which the essential element is the cancer cell. All the conditions connected with the tumour depend, directly or indirectly, on the behaviour of the cancer cells.

Phenomena of Cancer Growth.

The cells may fail to maintain themselves, in which case the tumour comes to an untimely end. They degenerate, shrink, waste, die, and are devoured by phagocytes. How often this happens no one can conjecture, but probably much more frequently than is supposed.† On the other hand, the cells may thrive, may grow and multiply, in which case the tumour extends its area. When it occurs in the substance of an organ, such as the breast, it may become quite a large lump, or if it occur in a limb around the bone it may attain an enormous size. Examine the structure of such a mass, and you will find that the cancer cells and framework have taken the place of the tissues which ought to be there. Fat, fibrous tissue, muscle, have disappeared, or are broken up and separated by groups and masses of cancer cells with their framework. Examine the tissues beyond the apparent limit of the tumour and you will often find isolated cells or groups of cells between the muscular fibres or in the minute or larger lymphatics.[3] (Fig. 8.) And you may find little

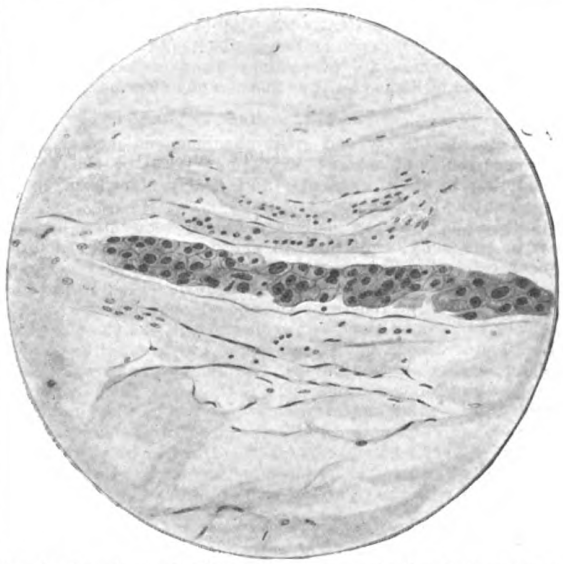

FIG. 8.—Lymph vessel filled with cancer cells (lymphatic permeation, from Sampson Handley), Cancer of the Breast, Pl. III, London, 1906.

masses of cancer cells projecting into the lumen of a blood vessel, the wall of which may be destroyed or still unbroken.[4] (Fig. 9).

These conditions are not discovered in all cases of malignant disease, even in all cases of the same variety of cancer of the same part of the body. In some cases not a single isolated cell or group of cancer cells will be discovered in the tissues beyond the apparent limit of the tumour. I do not say they are not there, but they are not recognised, so that they cannot be either large or characteristic. Where they are found, however, they may directly produce new phenomena, for a single cell or group of cells may grow to form a mass in the midst of the muscle or tissue where it lies.

Destruction of Natural Tissues.

The advance of the tumour is characterised by one great phenomenon—destruction. Every tissue which it attacks is destroyed, and replaced by the cancer cells and their suite. Hard tissues, soft tissues, vascular tissues, and tissues without vessels, are all destroyed—not all at the same pace or all precisely in the same manner. For such tissues as cartilage and elastic tissue resist the attack much longer than soft tissues, and even than bone. There is also indirect destruction of tissue whose nutrition is interfered with by the growth of the tumour. If the tumour makes its way towards the surface, the epidermis is raised and stripped off, and the mass of cancer cells is exposed. With the exposure of the cells a new series of events may be expected. Micro-organisms, bacteria and bacilli, gain access to the cancer cells. Sepsis, suppuration, ulceration, and sloughing take place, and the condition of the host is seriously prejudiced by these occurrences, which may even compass his death. Sometimes the tumour may shrink, and even when it is adherent to the skin may not break through. It undergoes atrophy from the wasting and death of the cells in its central parts. But it is not cured; for while the centre dies or withers the margin often flourishes and widens.

Resemblance to Attacks by Parasitic Protozoa.

In all these circumstances which attend the growth and development of the tumour there is nothing which

* Lecture I. was published in THE LANCET of Nov. 25th, 1911, p. 1457.

† Dr. Clowes spoke to me of this on the journey up from the meeting of the British Medical Association at Exeter in 1908, and suggested to me that recovery from an attack of cancer is probably not so very infrequent.

does not equally occur in the attacks of certain parasitic protozoa on their hosts—for instance, *Myxobolus cyprini* invades, destroys, and takes the place of the kidney epithelium of the carp; *Myxobolus pfeifferi* destroys and takes the place of the muscles of the barbel. It is the same story, common to both the cancer cells and to the protozoa which are not toxic—destruction of the natural tissues and their replacement by the cancer cells or parasite. And just as the masses formed by cancer cells are attacked by bacteria, and break down and ulcerate when they are exposed, so do the masses formed by *Myxobolus pfeifferi* break down from similar causes when they reach the surface of the body and are exposed. (Fig. 2.) All these phenomena of the tumour are perfectly intelligible if the cancer cell is accepted as an independent organism, pursuing the two great objects which are pursued by the parasitic protozoa—maintenance of itself and continuation of its species.

2. METASTASIS.

And now for the second great phenomenon—metastasis—the occurrence of masses in various parts of the body, resembling in their elements, and nearly always in their arrangement, the tumour.‡

Collections of cancer cells are found, sometimes in one part of the body, sometimes in another, composed, not of cancer cells of different varieties, but of cells of the same variety as those which compose the tumour. (Figs. 10 and 11, Figs. 12 and 13.) Wherever they occur they are associated with the same conditions as are observed in the tumour—the formation of vessels and a framework, and a satellite collection of other cells (leucocytes, lymphocytes, and the like). The grouping of the cancer cells is the same, the substances which they secrete, the degenerations which they undergo, the mode of reproduction—all are those of the cells of the tumour. Every metastasis is, as the Director of our Cancer Research has truly said, a reproduction of the tumour, and corresponds with the results of implantation.

Mode of Conveyance of Cancer Cells.

It is due to the presence of cells from the tumour in those parts of the body in which the metastases occur. On this matter there is practically no difference of opinion, nor is there any serious difference of opinion on the coarse mechanism of metastasis. The cells may be deposited on a surface which is constantly or frequently in contact with the tumour, may become fixed there, and may grow and multiply (auto-inoculation). They may be conveyed in the air or in the food, from the larynx to the lung, or from the stomach to the intestine, and may form metastases in either place. But these are exceptions to the general rule, and are of rare occurrence. The metastases which we see daily are due to the penetration of the cancer cells into the interstices of the tissues or into the lymphatic vessels, along which they spread, and to conveyance by the lymph and blood. They can often be easily demonstrated in the tissues, between the fibres of voluntary muscle, for example, and in the lymphatics. But it is well-nigh impossible to detect them in the moving blood and lymph, probably because it is the young and least characteristic cells which are conveyed, and there is so little to distinguish them by, especially when they are on the move. In spite of the absence of direct evidence the circumstantial evidence in favour of conveyance in the blood and lymph is so strong that it is not questioned, and I need not occupy time by repeating it.§

Variation in Number and Seat of Metastases.

Seeing the variety of the mechanism of metastasis, it is only reasonable to expect that there should be some variation in the number and seat of metastases. And so, indeed, there is. Sometimes the metastasis is limited to a single tiny nodule in a distant organ, sometimes to a few tiny nodules within a limited area; sometimes it is greater in bulk than the tumour, and sometimes it seems as if it had been scattered broadcast, without order or method. Nor is there greater uniformity with regard to time than in regard to seat and size. Metastasis may be present at the moment the tumour is discovered, or it may be deferred for years, or it may never occur in cases in which it ought to. No wonder such variations have been a puzzle to those who study cancer, particularly to the experimental investigators. It seems so inconsequent, so void of method, that it has led one of the most able investigators of the present day to aver that the study of cancer in man and animals is rendered peculiarly difficult by the extraordinary variety in the histology and clinical behaviour of the malignant new growths which attack them.[5]

Necessity for Separate Study of Each Variety of Cancer.

I do not agree with this statement. It rests on a misapprehension, on a false conception of cancer, on imperfect observation, and on the manner in which the life-history of cancer has been studied. If all varieties of cancer in all kinds of animals are studied higgledy-piggledy—squamous carcinomas, spindle sarcomas, spheroidal carcinomas, myeloid sarcomas—in man, and mice, and dogs, and rats, it is perfectly correct. It would be equally true of the parasitic protozoa if they were studied in similar fashion. If Sarcosporidiidæ, Myxosporidiidæ, Coccidiidæ were all jumbled together, and an attempt were made to describe the histology and clinical behaviour of the jumbled mass, the result would be confusion and profound perplexity. But no naturalist thinks of studying them in such a fashion. Each family is studied separately—not only each family, but each variety—and the characters and life-history of each is gradually deduced with clearness. Precisely the same method must be directed to the study of the organisms of cancer. Each must be studied separately. For more than 30 years I have insisted on the necessity of the separate study of each variety of cancer in the part in which it occurs.[6] And Mr. Stephen Paget more than 20 years ago, in an excellent paper in THE LANCET,[7] showed the necessity for this same separate study, particularly in relation to metastasis. To some extent this has been done by the clinical pathologists, and here are some of the results.

Some Characteristics of Different Types of Cancer Cells.

Take, first, a *round-celled sarcoma*. Let it be of the femur and subperiosteal. It grows very rapidly and is one of the most surely fatal of diseases. Amputate the limb above it, far above it, and take the bone out at the socket. It is, nevertheless, likely to return in the muscles of the stump. And even if it does not do so the patient will almost inevitably die from metastasis, even if the tumour was removed as soon as it was discovered.

Of all places the lungs are most likely to be the seat of the metastases. The femoral and inguinal glands are not usually affected. But metastases may occur in distant lymphatic glands, in the skin and subcutaneous tissue, in the liver—indeed, almost everywhere. Most of the patients are dead within a year or 15 months. And the instances in which a patient can be claimed to have been cured of this most terrible variety of cancer are so few that they can be counted in units.‖

Now, take a *spindle-celled sarcoma* of the testis—also a very deadly disease, but not to be compared in this respect to subperiosteal sarcoma of the femur. It forms a tumour, often large, in the cavity of the scrotum. It is easy to remove it, and there are many instances in which there is no recurrence in the stump and the patient is cured by the operation. But there are many more cases in which, at the end of an indefinite period—perhaps a year, two years, or more—a mass is discovered in the abdomen, which grows until it kills the patient. It is formed by metastasis in the glands, in the liver, and other viscera of the abdomen.

Take a *spheroidal-celled carcinoma* of the breast. The metastases will occur first and chiefly in the glands of the axilla, then in the liver and lungs, but particularly in the liver.[8] They may attack the bones—the sternum, the humerus, the femur, and the vertebræ—particularly the vertebræ of the lumbar region. And if the disease recurs

‡ Almost all the knowledge we possess of metastasis—in any case, the useful knowledge—is the result of clinical pathology, not of experimental observation or of laboratory investigation. This is, in itself, so good an excuse for the continued pursuit of clinical pathology and so admirable an illustration of its use that it alone would suffice to encourage clinical pathologists and to furnish proof that the day of clinical pathology is far from set.

§ There is really only one point on which there is grave doubt—whether the cancer cells are mere passive bodies in their migration or whether they are active agents (Bland-Sutton, Clinical Journal, 1910). As this does not affect the argument it is not necessary to discuss it now.

‖ Dr. Coley claims to have cured some cases of subperiosteal sarcoma of the femur by his injections. We have not been very successful in this country, and I only hear of a very occasional success from the use of Coley's fluid. But it is probable Dr. Coley and his pupils are more skilled in the management of the fluid than the English and continental surgeons.

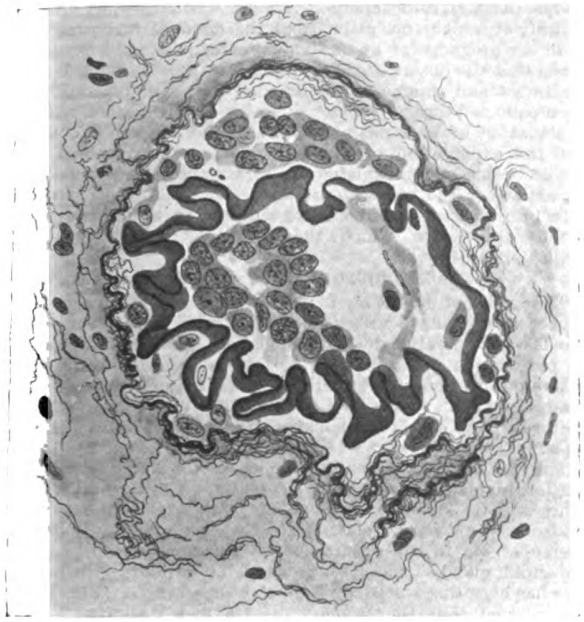

FIG. 9.—Cancerous infiltration of vessel wall (E. E. Goldmann). Studien zur Biologie der Bösartigen Neubildungen. Taf. IV., Tübingen, 1911.

FIG. 11.—Glands removed from same case (10)—duct cancer—at same time.

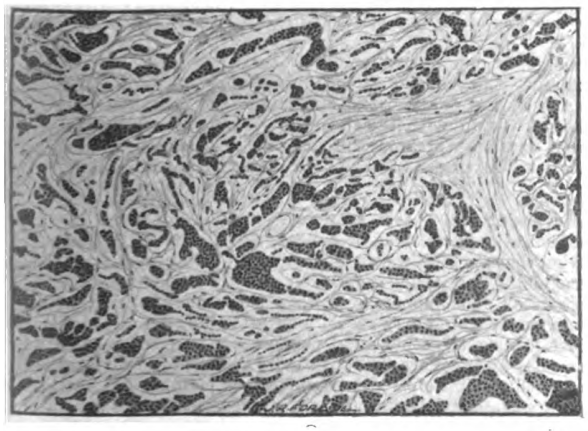

FIG. 13.—Recurrent nodule removed from muscle of same case (12). Removed October, 1900; patient well in 1906.

FIG. 10.—Duct cancer of breast.

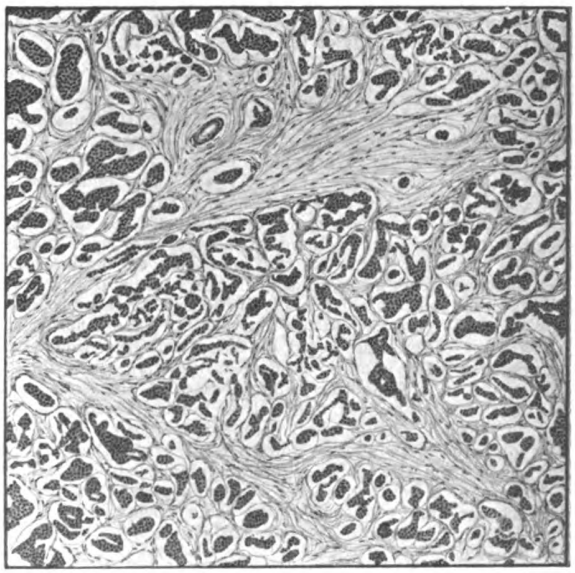

FIG. 12.—Spheroidal carcinoma of breast, removed December, 1896.

FIG. 14.—Squamous-celled carcinoma of the groin glands of a chimney-sweep, in whom no primary disease was discovered. This case is published by Dr. John Stacy, of Norwich, in the British Medical Journal, 1892, vol. ii., p. 578. After the death of the patient Dr. Stacy sent me slides cut from the glands. I do not know whether any similar case has been drawn.

in situ, it frequently forms numerous little flat nodules or plaques in the skin and subcutaneous tissue.¶ If the breast and glands are removed there may be no distant metastases. But the pathologist would be a bold or ignorant man who would assure the patient that the disease would certainly be cured by the operation. Again, take a *columnar-celled carcinoma* of the rectum. The metastases will be in the abdominal lymphatic glands and in the liver, in preference to any other part.

Take *squamous carcinoma* of the tongue, where the limitation of metastasis becomes much more restricted. It takes place in the neighbouring lymphatic glands, and sometimes in the glands on the opposite side of the neck. If the primary disease and the glands are successfully removed, so that there is no recurrence in tongue or glands, there is so little likelihood of distant metastases that they are practically left out of the account. The possibility is admitted, but the event is so infrequent that we do not fear it.

Finally, take *rodent ulcer* of the face. The extension of the disease beyond its apparent limit—the destruction effected by the cells—their tenacity of life and power of multiplication—have long assured for rodent ulcer a place among the malignant tumours. But the cells of which it is composed seem to be quite incapable of flourishing in any other parts than the immediate neighbourhood of the tumour, and there are no metastases. I do not say that metastasis never takes place, but it is so rare that its occurrence is not provided for in the pathology of the disease.

Similarity of Courses run by each Variety of Cancer.

Every case of a particular variety of cancer of a particular part of the body does not run precisely the same course as every other case of the same variety of cancer of the same part. Nor does every case of parasitic protozoon of a particular animal run precisely the same course as every other case of the same protozoon in the same animal. But compare a hundred cases of squamous carcinoma of the tongue with another hundred cases of the same disease of the same part, and let the conditions be similar for each hundred cases as regards operation, &c., and I venture to say that the resemblance of the second hundred to the first hundred cases would be marvellous. I am sure that no greater differences would be discovered than would be discovered if one hundred cases of *Sarcocystis miescheriana* were compared with another hundred cases of the same parasite in the same animal, and not so much difference as would be found if one hundred cases of *Myxobolus pfeifferi* were compared with another hundred cases, but the barbel were taken from two quite different streams. In the same way compare a hundred cases of carcinoma of the breast with another hundred cases of the same variety of carcinoma of the same part, and see how little difference there will be between them.

When studied in this fashion the results are so constant that we, the surgeons, presume upon them. We trade on them. We do not remove the lymphatic glands in cases of rodent ulcer because we are confident, however long the disease has existed, the glands will not become diseased. And we are equally confident that there will not be metastasis in any other part of the body. We remove the primary tumour and the associated glands for squamous carcinoma of the tongue, with the full assurance that if the operation is successful in preventing occurrence or recurrence in those structures, we shall save the lives of many of our patients. We amputate the breast, remove the muscle and the contents of the axilla, and dissect away wide areas of the fascia for spheroidal carcinoma. When the disease is not extensive or rapid in its course we expect to save the lives of more than half our patients. But we have not the same hope of the result of a successful operation as we have if the operation is successful in rodent ulcer or in squamous cancer of the lip. For the spheroidal cell may thrive and multiply in the liver, the lungs, and bones. And this may happen five or six or more years after the successful removal of the breast and the associated structures.**

So with regard to other varieties of cancer in various parts of the body. In all cases our treatment is adapted to what we know, or believe we know, of the course of that particular variety of cancer in that particular part of the body. And if it be charged against us that we are often wofully at fault in our estimate of the effect of an operation or in our prognosis of an individual case, it must be remembered that the observations on which our present methods of treatment and prognosis are founded have all, practically, been collected during the last 40 years or little more. The explanation of metastasis is migration of the cancer cells, and the explanation of the seat of metastatic tumours is precisely that which explains the occurrence and seat of the metastases of the parasitic protozoa—the penetration of the cells into those places which are suitable to their existence—those places in which they can live and thrive and multiply.

SOME PHENOMENA OF CANCER.

Time will not permit me to deal with all the phenomena of cancer as they have arisen before my mind in the course of the last few months, during which these lectures have been in preparation. I shall have to reserve some of them for future publication, and I shall also have to reserve the consideration of this theory as a working theory of cancer. But there are two or three phenomena to which I should like to refer.

The first has puzzled many pathologists for many years. I tried to explain it more than 20 years ago with indifferent success.[9] It is the occurrence of metastases without the evidence of primary disease. The best examples of it have been observed in the occurrence of squamous carcinoma of the groin glands in sweeps, in whom no primary growth or sore has been discovered by competent observers. (Fig. 14.) I suggested that the primary disease had "aborted"—in other words, got well—but not before some of the cells containing the material of cancer had been conveyed to the lymphatic glands. My explanation was very near the truth. That cancer should "abort"—get well—was not much in the minds of pathologists 20 years ago. To-day everybody knows that it does get well, both in animals and human beings,[10] and many of us are prepared to believe that it gets well much more commonly than we know of at present. But in these cases before it does so some of the cancer cells have already migrated to the groin glands and have made good their footing there.

The occurrence of ossification, calcification, and chondrification in many of the sarcomata, is a phenomenon which has never puzzled me when the tumour is connected with a bone, or when the metastasis is of a tumour growing from a bone. It seems natural—only what might be expected—that the framework of such tumours should contain bone or cartilage. But I confess it has puzzled me when the tumour is of a part which has no connexion with bone or periosteum. For instance, such a tumour is sometimes—though very rarely—found in the female breast. Why should cells derived from the glandular or connective tissue of the breast command a framework or scaffolding in which bone or cartilage cells are prominent constituents? Bashford explains it on the grounds that such conditions occur in association with inflammatory processes. He shows how frequently it occurs in mammary tumours in the dog, and says:

> It seems to demonstrate that the connective tissue of the dog is very liable to such metaplastic changes, just as the connective tissue of the rat or of the mouse is liable to the changes characteristic for these animals.[11]

There is one phenomenon of cancer which no theory explains—the constancy with which spontaneous cancer begins at one point instead of many. It can scarcely be made to fit in with the theory of "removal of restraint," but it does not threaten the stability of this, or many other theories. At present I have no explanation to offer of it.

APPLICATION OF THEORY.

Reviewing, in a few sentences, the application of this theory to the phenomena of cancer, I will not undertake to affirm that all the known phenomena of cancer can at once be explained by it, but it *does* offer a ready explanation of the first great phenomenon of cancer—the tumour—and of all the changes which may occur in it. It offers an explanation of metastasis, the other great phenomenon of cancer; of the reasons why it occurs; why it occurs in one place rather than in another; of deferred metastasis; of metastasis without primary tumour. In fact, it explains so simply so many of the phenomena of cancer that it is necessary to make diligent search to discover the two or three phenomena which are

¶ The mechanism of these metastases has been very well described by Mr. Sampson Handley in his book on Cancer of the Breast.

** In speaking of "successful operations" in the preceding paragraphs, I hope it will be understood that I am only referring to the success of the operation in preventing recurrence in the parts which were diseased.

not explained by it. And of these it may be said that there is not one of them which endangers the acceptance of the theory, and that they are equally inexplicable by any other theory which has yet been advanced. It fulfils also the conditions laid down by a writer in the *British Medical Journal*,[12] who pointed out that, to make my case good, my parasite must be tried by the laws laid down by Koch—to wit, "A specific micro-organism must be constantly associated with a given disease; it must be isolable and studiable apart from the disease, and when introduced into a healthy animal it must be able to reproduce the disease in that animal, and in the animal in which the disease has thus been experimentally reproduced the organism must be found under the original conditions." It fulfils these conditions with a fidelity which is remarkable. The only one of them on which any dispute could arise would be whether the cell is "isolable and studiable apart from the disease" in the sense in which Professor Koch used the expression. If that is all that is lacking we are not likely to have to wait long for it. Indeed, Carrel and Burrows maintain that they have already solved that problem in the Rockefeller Institute of Medical Research.††

I now come to the last part of my task:

WHERE DOES THE CANCER CELL COME FROM?

Six years ago[13] I summed up the evidence in favour of the only two views which could reasonably be put forward: *Entrance from without* or *formation within* the body; and came reluctantly to the conclusion that the evidence of "formation within" was stronger than the evidence in favour of "entrance from without." I say "reluctantly," because it led to the logical conclusion that new species of living creatures are created from a source and in a manner which has never hitherto been imagined. Nevertheless, during the last six years the evidence in favour of "formation within" the body has grown steadily stronger, while nothing has been added to the evidence in favour of "entrance from without."

Evidence of "Formation within" the Body of Cancer Cell.

I cannot stop to dwell on the points of each piece of evidence, but must content myself with enumerating them:—1. The resemblance of the cancer cells to those of the natural tissues in which the cancer appears to start. 2. The resemblance of the secretion of the cancer cells to the secretion of the natural cells. 3. The resemblance of the degenerations of the cells to those of the normal cells (fatty, caseous, calcareous, &c.). 4. The resemblance of the grouping of the cells to the grouping of the natural cells. 5. The resemblance of the phenomena of reproduction in the cancer cells to those of the natural cells which they resemble. All these may be regarded as traits of atavism, and it is upon these that the explanation of some of the phenomena of cancer rests.

Explanation of Conduct of Cancer Cell.

Students of cancer, research workers, biologists who have studied cancer, are all practically agreed that the cancer cell is derived from the cells of the part in which it takes its origin, or appears to take its origin, and they are bent on finding an explanation of the reasons which lead the cancer cell to behave so differently from the cells from which it is derived. Escape from natural restraints—the acquirement of the habit of growth—the theory of embryonic rests—chemical stimulation—a self-contained and ordinarily invisible micro-organism living in symbiosis with the cell—these are some of the theories by which learned men have sought to explain the strange conduct of the cancer cell.

Empty phrases! They might account for variations in colour, size, shape, secretion, degeneration, physical activity—for a multitude of the variations from the normal cell exhibited by the cancer cell—but how can any of them account for the vital difference which I will express in two short sentences? Implant the normal cell, and you cannot make it live. Implant the cancer cell, and you cannot kill it.

There is one, and only one, explanation of the conduct of the cancer cell—that it has been endowed with that wondrous gift which no man has seen and which no man can understand—the gift of life; and that, owing to that gift, it has become an independent creature, a new creation of living thing. The host in which it dwells has fashioned it out of his own tissues and in the likeness of his tissues and, to borrow the figurative language of Scripture, the Creator has breathed into it the breath of life, and it becomes a veritable Frankenstein's monster, bent on the destruction of its host. After ages of past and present civilisation, during which searchers and philosophers have sought to explain the origin and nature of life, we have come no further than this, and he who discovers the true origin of cancer will have solved the enigma which has hitherto baffled the searchers and philosophers in all ages and of all countries.‡‡

"*Unicellula Canori.*"

If the cancer cell be in truth a new creature, to what class of creature does it belong? It is nearest to the protozoa—so near, indeed, that it is difficult to keep it out of the protozoa. Every new observation of the last six years—every new discovery—has brought it nearer to the protozoa. But the biologists will have none of it. I must therefore make a special place for it and provide it with a name. It shall be *Unicellula canori*. And for the different varieties the shape of the cell can be expressed in simple terms which will be familiar to us all. On the one hand, *Unicellula* (*canori*) *squamosa*, *Unicellula spheroidalis*, &c.; on the other hand, *Unicellula* (*canori*) *fusiformis*, *Unicellula rotunda*—and so on. These names will serve still, even if the cells eventually join the great phylum of the protozoa.

I am perfectly conscious of the far-reaching consequences of admitting that unicellular bodies derived from such a source are a new species of created beings, but there is no alternative. The facts are plain, and cannot, I believe, be otherwise interpreted. If the theory is false, I can only say it is very remarkable that it should explain, in so satisfactory a manner, the chief and nearly all the subordinate phenomena of cancer.§§

A Parable.

In conclusion, I should like to tell you a parable. A learned professor, walking in the desert, observed a curious little object on the ground. It had a rounded snout and flattened head, large eyes, a flattened body, short fore-legs and very long hind-legs. It sometimes walked and sometimes jumped. The professor asked whence it came, and it replied: "I am a child of the desert, born of the grains of sand." This astonished the learned man. He took it home with him, and called together many of his friends, and set the little beast in their midst. They all looked at it, and said it must be a frog, for it looked like a frog, and behaved like a frog, particularly in its ability to jump. But when they heard its origin they were all amazed, and each one gave his explanation of the occurrence. One said, "It is a changeling; it is not what it looks to be." Another said, "It was surely made to swim, for its feet are webbed, and having no water to swim in it has acquired the habit of jumping." A third said, "It has been gingered." A fourth said, "Some restraint must have been taken off it to enable it to jump." And the professor himself said, "No, it has a flea inside which lives within it as its familiar spirit, and that gives it the power of jumping." Then the professor said to the little object: "We are very sorry for you. You are neither animal nor vegetable, for neither animal nor vegetable can be created from the sands of the desert. There is, therefore, no place for you among living creatures." The little creature jumped and crawled away. But as it did so it looked back at the group of learned men, and said: "There is no place in the living world for me owing to the misfortune of my birth. Thank you, gentlemen, but I have already found a place for myself, and you will find it very difficult to oust me from it."

THE FIRST AND LAST KINK IN CHRONIC INTESTINAL STASIS.[1]

BY W. ARBUTHNOT LANE, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO GUY'S HOSPITAL.

I AM very conscious of the honour you have done me in asking me to address you on this occasion. I have chosen the subject of chronic intestinal stasis since it has occupied my attention for many years, and because it promises to throw a great light upon disease. The causation of intestinal stasis, its symptoms, and the deleterious influence it exerts on the several tissues of the body, are full of interest for us. In a communication of this sort one must necessarily go over much material recapitulated many times before, but this is, I fear, unavoidable in the circumstances.

By chronic intestinal stasis I mean such a delay of the contents of the gastro-intestinal tract as involves the absorption into the circulation of a quantity of toxins greater than can be dealt with effectually by the organism. This condition of defective drainage may affect any portion of the gastro-intestinal tract, and in a degree which varies considerably with the locality of the obstruction. While the delay may be general there is usually one point where the obstruction is more marked than elsewhere. Sometimes the obstruction may be definitely local It is purely mechanical in character. In early life it is produced by abnormal distension of the intestine as a consequence of too frequent feeding and of unsuitable articles of diet. Later it is determined and exaggerated by the erect posture of the trunk, which in our state of civilisation is constant during our waking hours.

I wish now to call attention particularly to the great importance of the last kink or obstruction which is developed in our drainage scheme and which affects the large bowel where it crosses the brim of the true pelvis on the left side. The fuller recognition of the function of this kink, the lowest in position, has helped me to understand the physiology of the large bowel both in the savage and civilised communities. It has also enabled me to deal surgically with the conditions of defective drainage of the intestine more effectually and at less risk to the life of the individual than I was previously able to do. This kink develops very early in life; indeed, I believe the bands which form on the outer surface of the mesentery of this portion of the large bowel, and which, like all the other acquired mesenteries and adhesions, are the crystallisation of lines of resistance to downward displacement, are the earliest to form in the body. They appear before the erect posture is assumed. I have found them excellently developed in a child 2 years of age whom I short-circuited for extensive tuberculous disease of the hip-joint. This band obviously develops in order to resist the tendency to the downward displacement of the large bowel into the true pelvis, where it would seriously incommode the functioning of the several organs which already occupy it. As this new band or mesentery contracts and becomes a definite ligament quite distinct from the normal mesentery, on whose outer aspect it exists, it fixes the large bowel securely at this level and performs a function of the greatest importance. It is so arranged as to oppose the backward passage of fæces from the pelvic colon upwards into the large bowel, which is likely to take place if this kink or obstruction is not efficiently developed. It is often supposed that fæcal matter moves continually onwards in its progress through our intestines. That this is not always so is shown exceedingly well in those cases in which this particular kink or obstruction is not developed.

When I first performed ileo-colostomy for chronic intestinal stasis I divided the ileum and put it into the sigmoid loop, as it was usually the portion of the large bowel most readily and safely adapted for the performance of this operation. At the same time I took great precautions to free that obstruction at the pelvic brim to which I have just called your attention by dividing the new mesentery and by suturing it over in such a way as to try to obviate its re-formation. This operation was frequently followed by the passage of material back along the descending, transverse and ascending colon to the cæcum, often necessitating the removal of the large bowel at a later date. Owing to the recognition of this fact I then removed the large bowel down to a level of the junction of the ileum with the sigmoid, performing both operations at the same time. The only objection to this operation was the occasional development of adhesions between the small intestine and the abdominal parietes. When these adhesions develop they are liable sooner or later to cause symptoms of obstruction, as manifested chiefly by pain and distension. If it were not for the occasional development of these inflammatory adhesions the operation of the removal of the large bowel would be accompanied by little or no risk.

It was clear that if I could obviate the back flow of fæcal matter into the large bowel above my junction I would avoid the removal of the colon in a great number of cases and reduce very materially the risk of the operation. I then determined to effect a communication between the ileum and the large bowel in the true pelvis below the level of the last kink. This I found most successful. In many cases the operation was very easy to perform, since, in a large number of cases, the stasis is due chiefly to a progressive elongation of the pelvic colon. This elongated rectum puddles in the floor of the pelvis, and its contents are expelled with the greatest difficulty by any increase of the intra-abdominal pressure, however great the expulsive effort, since it acts at such a mechanical disadvantage. In consequence of this arrangement the rectum elongates very considerably. In a child operated on for extensive tuberculous disease of the hip the loose pelvic colon measured about 39 inches.

I believe that no one can become affected by tuberculous disease or by rheumatoid arthritis unless the resisting power of the individual to the entry of organisms has been depreciated by auto-intoxication consequent on the presence of chronic intestinal stasis. So in these conditions, and especially in the case of progressive tuberculous affections of joints, I employ no local operative procedure to the affected joint other than rest, and, if necessary, aspiration of any fluid material that does not readily become absorbed after the operation, but proceed to free the patient of the auto-intoxication by putting the ileum into the pelvic colon below the kink at the brim of the pelvis. In these cases the results of the operation have been most successful and the patient has improved both locally and generally. In one case we were surprised to find that the weight of the patient did not increase nor the local trouble improve in the marked manner we were accustomed to expect. The causation of this was readily determined by the X ray examination of the child after the administration of four ounces of bismuth by the mouth.

The systematic examination at frequent intervals of the patient by means of X rays after the administration of six ounces of carbonate of bismuth by the mouth in the adult and of four ounces in the child, is performed in every case before and after operation, every precaution being taken to render the state of the patient as normal as possible. In the case of the tuberculous child which obtained but little benefit for a period from ileo-colostomy, it was found that the fæcal material reached the rectum in the normal time. It accumulated there for a time, but instead of being evacuated a portion commenced to ascend the large bowel, some of it going as far as the cæcum. It was noted in this case at the time of the operation that the acquired band of peritoneum which produces the kink at the pelvic brim had not developed. It seemed as if the child could not be effectually relieved of the auto-intoxication from which she suffered unless the large bowel were removed, or a kink made artificially in its normal position by means of a running suture. Fortunately a regular evacuation of the rectum was obtained by the employment of a glycerine enema and a small quantity of aloes, and we hope in this way to educate the rectum to evacuate its contents, and so obviate the auto-intoxication kept up by the regurgitation of fæces into the large bowel.

I learnt from this case that the kink not only affords an obstruction to the downward passage of fæces from the sigmoid into the rectum, but that its chief action is to

[1] A paper read before the Derby Medical Society on Oct. 17th, 1911.

obviate the ascent of fæces from the rectum, which, I believe, occurs normally to a considerable extent in many people. I have found many patients complain that if they are prevented from evacuating the bowel when they feel the desire they are unable to do so for a long time, sometimes not till the usual time next day. I think it probable that an X ray examination with bismuth will show that in these cases fæces ascend from the pelvic colon into the sigmoid. I therefore determined that when the acquired ligament was absent or imperfect I would construct such a kink having the same position as the acquired band. This I have done by means of a suture passed through the outer wall of the bowel, through the mesentery and through the peritoneum of the iliac fossa. This has enabled me to deal with such patients effectually without exposing the patient to the added risk entailed by the removal of the large bowel.

While in these tuberculous cases the establishment of a direct junction of the end of the ileum with the side of the rectum is performed at little or no risk, and with considerable facility once the details of the operation have been mastered, the formation of the same anastomosis in the case of an adult, especially in a fat male subject in whom the rectum is fixed firmly to the wall of the pelvis and has no sort of mesentery, may be one of the greatest difficulty.

The accurate closure of the peritoneal interval between the ileum and the rectum is a matter of vital importance. I did not at first recognise the necessity of shutting off this interval. It seemed to me that the space between the two intestines was so great that no obstruction could arise however much bowel passed through it. I found that in some cases the operation was followed by frequent motions. This is most unusual, since, owing to the tenuity and laxity of the intestinal walls, it is not infrequently necessary to use paraffin or a drug to obtain a daily evacuation. On opening the abdomen I found that the prolapse of the small intestine into the pelvis had produced a torsion on its long axis of the terminal portion of the ileum where it entered the side of the rectum. This reduced its lumen and so produced the disability which led to frequent and painful evacuations. The closure of the interval between the intestines at once removed the trouble and restored the patient to comfort.

An œsophageal tube is passed up the rectum into the ileum through the junction. This by facilitating the passage of fæcal matter through the junction and by draining the small intestine of its gaseous and fluid contents has served to reduce the risk of this operation to a minimum. It is fastened in position by a suture which in the female is best passed through the back of the labium, since this part is much less sensitive than the skin in the vicinity of the anus. It is retained in position for six days.

As soon as the anæsthetic is commenced several pints of normal saline solution are introduced into the subcutaneous tissue of the axillæ. The absorption of this fluid serves to raise the blood pressure, and so reduce any shock to a minimum. Probably for the same reason the operation is very rarely followed by vomiting. It also serves to nourish the patient till food can be readily taken. It can be repeated without discomfort if necessary. The young child apparently sustains no shock whatever from the operation, and as soon as the period of anæsthesia is passed a distinct improvement in the child's mental condition is patent to everyone. (At the Hospital for Sick Children, Great Ormond-street, where we do a number of these operations on patients suffering from progressive tubercle, and who are distinctly on the down grade, the degree of stasis is determined by bismuth in every case before and after operation. These with the weight charts afford excellent evidence of the benefit resulting from the altered drainage. These are being collected and classified by Mr. Barrington Ward, the medical superintendent. The X ray photographs are taken by Dr. Ironside Bruce.) The bowels act regularly; the appetite improves wonderfully. An appearance of health replaces that of disease, and the weight of the patient goes up in a remarkable manner.

I think I need hardly remind you of the influence exerted by the auto-intoxication of chronic intestinal stasis in the circulatory and cerebral system, as well as on all the tissues of the body. I would allude particularly to the influence on the female breast. I regard the degenerative condition of that organ as manifested by induration, cystic change, &c., as a barometer of the degree of stasis in the individual. The degree of this degenerative change is influenced very materially by the colour of the hair and by the amount of absorption of prostatic secretion. The great importance of this latter factor is one that will sooner or later be impressed on the mind of the profession. I am uncertain whether the administration by the mouth of prostatic extract is likely to afford a result similar to that produced by thyroid extract. It is made in tabloid form by a firm in Chicago, and it is used very largely in the United States and elsewhere. Time will show whether this method of introducing the very stimulating extracts of this organ is of service or not. I have no doubt whatever that these degenerated breasts are very liable to develop cancer. I have found multiple foci of cancer in such degenerated breasts in cases of chronic intestinal stasis in which there was no reason whatever to suspect their presence.

That many find a difficulty in realising the causal relationship of chronic intestinal stasis with these breast conditions and other similar conditions is well illustrated by the elaborate report presented to the International Congress at Brussels by the distinguished French surgeon Paul Segond.[2] While accepting the general principles laid down he takes some exception to the causal relationship of intestinal stasis to what I would call "end results." Dr. F. Lejars also discusses the subject at length.[3] The views he expresses are in accordance with those of Segond. He refers very largely to a very careful study[4] of 50 cases of chronic intestinal stasis made by Mr. Harold Chapple. Mr. Chapple had assisted at a considerable number of these operations, and he had himself thoroughly investigated the career of each up to the date of publication. These form only a portion of the number of cases I have operated on, but they were the only ones that he was at that time able to see and investigate personally. He has also published an account[5] of several cases of progressive tuberculous disease treated by ileo-colostomy.

Before leaving the subject I would remind you of the obstruction that so frequently develops in the end of the ileum and which plays such an important part in the production of the group of symptoms which are regarded by the physician as evidence of indigestion. This so-called indigestion is entirely and solely mechanical in its origin and is chiefly due to the development of this obstruction at the end of the ileum. Besides the minor effects of the damming back of contents resulting from this kink we have the development of the duodeno-jejunal kink, the dilatation and inflammation of the duodenum, the dilatation and inflammation of the stomach, which not infrequently leads to the development of cancer of this organ, the infection of the biliary and pancreatic ducts, followed by the formation of gall-stones, pancreatitis, and by cancer of the biliary ducts and pancreas. This explanation of the causation of duodenal ulcer, &c., shows the futility of gastro-enterostomy except for mechanical obstruction.

I have dealt with this kink and its consequences in several papers,[6] and Dr. Franklin Martin[7] and Dr. Charles Mayo[8] have also published their observations on the subject. The latter paper contains beautiful illustrations of the condition, and I cannot close these remarks without acknowledging the very valuable assistance we have received from Dr. A. C. Jordan, who has done much excellent work in tracing bismuth meals by X rays through our patients. He has written two papers[9] which deal very fully with many of the appearances in chronic intestinal stasis.

THE ASSOCIATION OF HYSTERIA WITH MALINGERING:

THE PHYLOGENETIC ASPECT OF HYSTERIA AS PATHOLOGICAL EXAGGERATION (OR DISORDER) OF TERTIARY (NERVOUS) SEX CHARACTERS.[1]

BY F. PARKES WEBER, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE GERMAN HOSPITAL, DALSTON.

HYSTERIA was at one time, as the derivation of the word from the Greek ὑστέρα (uterus) shows, regarded as a disorder connected with the female sexual organs, but the frequent occurrence of similar symptoms (hysteria being sometimes as pronounced in males as in females) has long since proved that the idea of the exclusive connexion of hysteria with the female sexual organs is absurd.

Phylogenetic Aspect of Hysteria.

Sex characters may be divided into: (1) primary, those concerned with the sexual organs; (2) secondary, those concerned with the breasts, the facial hair, the features, the voice, the form of the skeleton (e.g., the shape of the pelvis and the cubital angle of the outstretched upper extremity), the development of the skeletal muscles, and the general conformation; and (3) tertiary. By tertiary sex characters I mean those dependent on the nervous system, including both characters of instinct and characters of mind (reasoning). Such nervous characters, unlike primary sex characters, are not the exclusive property of either sex; they are called male or female characters merely accordingly as they predominate in one or the other sex. From the phylogenetic point of view I believe that hysteria, or rather much of what is now grouped together as hysteria, may be regarded as a pathological exaggeration (or disorder) of certain tertiary (nervous) female sex characters.

According to this (phylogenetic) conception the exaggeration (or disorder) of so-called tertiary female sex characters in the male would account for occasional cases of "male hysteria." I am not here concerned with the temporary "hysterical" conditions not rarely observed in the male as the result of violent emotions, starvation, and grave nutritive disturbance, or as forming a familiar part of the effect of certain toxic substances such as alcohol. The phylogenetic aspect of hysteria is, as far as I can see, not necessarily opposed to Pierre Janet's, Babinski's, and some other modern views on the subject.

Pathomimia.

I shall not trouble to bring forward any special evidence here to prove that ordinary hysterical symptoms are frequently associated in the same patient with attempts to simulate disease, accident, or injury, and with deception of all kinds ("mythomania," &c.). The fairly frequent occurrence of such association is recognised by all; so much so, that in a recent paper on Hysteria and Mythomania Dupré and Logre quote Hartemberg as maintaining that hysteria (which Charcot called "la grande simulatrice") "est d'essence mythopathique; elle peut se définir la *mythomanie des syndromes*."[2] Moreover, the frequent use of the term "hysterical malingering" or "hysterical simulation" proves that the occurrence of such associations is generally acknowledged.[3] In fact, hysteria is frequently characterised by two kinds of simulation of disease, or "pathomimia," if I may be allowed to borrow a term suggested by Paul Bourget for his friend Dr. Dieulafoy, who employed it in one of his most sensational medical communications:[4] (1) the unconscious mimicry of disease, so well referred to in the writings of Charcot, Sir James Paget, &c.; and (2) the conscious, more or less voluntary, imitation of disease that may be termed "hysterical malingering."

Hysterical Malingering.

I need simply explain my conception of hysteria and my view of the kind of simulation so frequently associated with it ("hysterical malingering") in order to show what I believe to be the pathological connexion between the two, though it is possible that some of the multitudinous morbid phenomena which have been described by various authors as "hysterical" may find no place in my scheme. To avoid confusion I shall refer only to such universally recognised features or symptoms of hysteria as: (*a*) "functional" muscular paralyses and spasms and hysterical convulsions; (*b*) hysterical pains and paræsthesiæ (hysterical "clavus," "globus," &c.); (*c*) hysterical disorders of the circulatory system (hysterical palpitation, pulse irregularity, and vaso-motor disorders); (*d*) the well-known suggestibility of hysterical persons and loss of spontaneous will-power. I maintain that all these features or symptoms of hysteria can be explained as resulting from pathological exaggeration (or disorder) of tertiary (nervous) female sex characters—characters which, in normal degree, might have been useful in regard to selection by the other sex.

Thus (*a*) and (*b*) may be regarded as exaggerations of the slight ailments to which the "weaker sex" are supposed to be naturally more liable than the "stronger sex," and which call for the sympathetic interest of the protecting males. Some at least of the hysterical symptoms grouped under (*c*) may be regarded as representing an exaggeration of the normal vaso-motor excitability ("erethism" if more than normal) of young females (including facile blushing and responsive emotional changes in pulse frequency), which constitute part of their attractiveness to the other sex. So also (*d*) may be regarded as an exaggeration of the tendency of the female mind to bend to the opinion of (male) authority, a tendency which when recognised as present is (or has been) often gratifying (flattering) to the male.

I now come to the question of "hysterical malingering" and all kinds of deception and simulation without any adequate rational cause. In past ages (from early prehistoric times onwards) simulation or deception of various kinds must often have been serviceable to the weaker female in protecting herself from the stronger (and sometimes cruel) male, as well as in enabling her sometimes to get her own way by "getting round" her male partner. By a natural process of "survival of the fittest" the facility for effective deception would, in a barbarous age, persist or gradually increase in the females—that is to say, it would become a tertiary sex character; and it must be recognised that the average female of the present day seems not to have altogether lost this inborn aptitude for deception.

Of course, deception and "tricks" of various kinds were also often useful to the male in his struggle for life, but they were more necessary to the female, and therefore at the present time the facility (instinct) for deception is probably greater in the average female than in the average male.[5]

In both sexes this tendency to deceive is normally from an early age kept in check by the exercise of memory and reason, but in many hysterics the tendency in question is present in such an abnormal (pathological) degree that it cannot be suppressed. Such persons practise simulation and deception of various kinds without any adequate (rational) grounds, and such "hysterical malingering," hysterical "mythomania," &c., may be justly regarded, I think, as an exaggeration (or disorder) of an instinct resulting by a process of survival of the fittest from the necessities of our primitive ancestors (especially female ancestors). According to this view the greater frequency of such "hysterical malingering," "hysterical mythomania," &c., in women than in men is explained as a result of the fact that the tendency or facility (instinct) for deception is normally greater in women than in men.

Relationship of Deception to Hysteria.

From my point of view, therefore, the intimate relationship of deception (without adequate rational motives) to hysteria is clear. I would, in short, claim that most (but not necessarily all) of the phenomena ordinarily classed under the heading "hysteria" are dependent on a special kind of instability of the nervous system and may be regarded as the

---

[1] A paper read before the Medical Section of the Royal Society of Medicine on Nov. 28th, 1911.

[2] Proceedings of the Twenty-first Congress of Alienists and Neurologists, 1911, Presse Médicale, Paris, August 12th, 1911, p. 660.

[3] I am about to publish elsewhere two remarkable cases which I have had an opportunity of following over a great number of years and which illustrate the intimate association of simulation and hysteria. Hysterical anæsthesia and hysterical paralysis occurred in both cases.

[4] Communicated to the Paris Academy of Medicine, June 9th, 1908; Presse Médicale, Paris, June 10th, 1908, p. 369.

[5] H. Campbell ("Differences in the Nervous Organisation of Man and Woman," London, 1891, p. 54) writes: "Women, it has been said, are born actors. May not the cunning and dissimulation so frequently found in the hysteric state be in some measure attributable to an innate tendency in this direction, evolved in the manner indicated?"

expression of a pathological exaggeration or disorder of certain tertiary (nervous) sex characters, the presence of which in normal degree can be accounted for on a phylogenetic or evolutionary basis.

Some at least of the normal tertiary sex characters are psychical and are due to hereditary functional properties of the higher central nervous system, functional properties which have gradually developed as the result of sexual selection and the survival of the fittest in past ages. The tendency to simulation and deception (without adequate motive) characteristic of some hysterical subjects may be regarded as an exaggeration (or disorder) of an instinct which is normally greater in women than in men, the greater prominence in women of the tendency or instinct to deceive constituting a normal psychical sex character. Such psychical sex characters, whether normal or hysterical (i.e., exaggerated or disordered), are not acquired by means of memory and reason, but are inborn or developmental "instincts," the term "instincts" being here applied to functional reactive properties of the higher psychical portion of the central nervous system, reactive properties which have been acquired not owing to repeated ancestral, voluntary, or rational efforts, but simply owing to the laws of evolution acting by the survival of the fittest.

Like other instincts (for instance, the instinct of self-preservation) they may be to some extent controlled by the exercise of memory and reason and, on the other hand, may be rendered conspicuous and dangerous to their possessor (or their possessor's neighbours) by influences such as mental and physical overwork and shocks, which weaken the normal rational action of the mind in its restraining influence over the instincts. The therapeutic preventive indications are, therefore, largely educational, but prevention in such matters can obviously only be rendered really effectual by means of sexual selection and eugenics; in fact, just as sexual selection in the past is responsible for the existence of the tertiary (nervous) sex characters and their abnormal variations of the present day, so sexual selection in the present and future will modify the nervous sex characters, as well as all other instinctive nervous tendencies of future generations.

Concluding Remarks.

My brief exposition of what I call the phylogenetic or evolutional conception of hysteria, as being due to an exaggeration (or disorder) of tertiary (nervous) female sex characters, has also, I hope, explained why hysteria (according to my conception of hysteria) is so frequently associated with a tendency to simulate disease, accident, or injury, or deceive in some kind of way in the absence of any adequate (rational) motives.

I would here repeat that the so-called tertiary (nervous) female sex characters, though naturally best marked and most striking in the female sex, are not the exclusive property of the female sex. They occur likewise, though they are usually less conspicuous, in the male sex, and it is by their occasional exaggeration (or disorder) that I explain the occurrence of hysterical and irrational (apparently motiveless) deception and simulation ("hysterical malingering") in males.

Teleology (that is to say, the modern Darwinic or evolutional idea of teleology) finds a place in the phylogenetic aspect of hysteria, and it seems to me also to claim a place in regard to other conceptions (Babinski, Freud, Janet, and others) of hysteria. For instance, is it not conceivable that hysterical excessive suggestibility may, on the whole, be useful rather than harmful for persons whose own will-power is pathologically deficient? Moreover, in cases in which wretched experiences have made their psychical marks or "psychical traumata" in the past, and in which the present condition is in some way gravely affected by subconscious reminiscences, "separation of consciousness" may be supposed to bring not only inconveniences and dangers, but also a certain kind of relief.

Some functional nervous symptoms usually classed as hysterical are not readily explained by my conception of hysteria. So-called "hysterical vomiting" seems to be a pathologically exaggerated action of the reflex defensive mechanism by which poisonous or irritating ingesta are normally rejected. But it may sometimes be on the borderland between hysteria and voluntary action simulating disease.[6]

[6] Cf. F. P. Weber, remarks in Brain, London, 1904, vol. xxvii., p. 193.

Furthermore, in regard to the greater frequency of simulated diseases, self-inflicted skin lesions, &c., in women than in men (I do not, of course, here refer to simulation of diseases and accidental mutilations in cases in which the simulation is attempted for obvious reasons, such as to escape military duty in countries where conscription is practised) it may be remembered that when a woman is depressed and altogether discontented with the life she has to lead, she is more likely than a man would be to try to attract attention or pity by simulating disease or injury. A man usually has much more open to him; he can seek a new country or (if he does not endeavour to obtain relief by drink or gambling) he can take part in dangerous ventures of various kinds which bring excitement and temporary relief.

ACUTE OSTEOMYELITIS OF THE VERTEBRAL COLUMN.

BY FORBES FRASER, F.R.C.S. ENG.,
SURGEON TO THE ROYAL UNITED HOSPITAL, BATH;
AND
THOMAS McPHERSON, M.D. McGILL, F.R.C.S. ENG.,
FORMERLY HOUSE SURGEON TO THE HOSPITAL.

REPORTS of cases of acute osteomyelitis of the spinal column are rare, at least in this country, and it is thought that the following account of a successful operation for this condition may be of sufficient interest to justify publication.

A boy, aged 9 years, previously in excellent health, fell on his right buttock in an asphalt yard on Sept. 21st, 1909. The accident was not a serious one, and though he complained of pain and stiffness he was able, after rubbing with embrocation, to walk without discomfort on the following morning. After a few hours, however, the pain came on again, and he was seen by Mr. W. G. Mumford, who found nothing more than such as to suggest an ordinary bruise or sprain. The boy was kept in bed and treated with hot fomentations, but on the following day he had diarrhœa, and in the evening his temperature rose to 104° F., and the pain in the back and buttock became much more acute. On the next day the temperature was still 104°; the boy was delirious and had extremely acute pain and tenderness in the left lumbar region. There were also some abdominal pain and distension, but nothing definite could be made out in the abdomen or the chest.

The patient was then admitted to the Royal United Hospital, where he was first seen by us. He lay perfectly flat on his back, without a pillow, and with his left thigh flexed on his abdomen. His face was flushed, his eyes staring, and his expression that of intense anxiety. His breathing was rapid and shallow, his pulse 84, temperature 103°, and his tongue coated but moist. No physical signs were present in the chest or abdomen. The pupils were equal and reacted, and there was no optic neuritis. He complained of intense pain in his back, and any attempt to extend the thigh or to raise the head caused him to shriek with pain.

On examining the back there was seen to be very slight fulness in the left ilio-costal space, and two inches to the left of the third lumbar spine there was a point of particularly acute tenderness. The spines themselves were not tender to pressure or percussion, and as far as could be seen the column was moveable when the boy turned on his side. No evidence of disease of the hip-joints or sacro-iliac joints was present, and pain was not elicited by jarring the spine by forcibly thrusting the femur against the acetabulum. There was no paralysis of the lower limbs and no affection of sensation could be made out. No tendon reflexes could be elicited, but the superficial reflexes were present, and the plantar reflex gave an ill-defined extensor response. The rectum and bladder were under proper control and the urine was normal.

The diagnosis being uncertain hot fomentations and salicylate of soda were ordered, but the boy kept the whole ward awake at night by his shrieks, and on the following morning his condition had decidedly changed for the worse. He was now more or less delirious, there was some retraction of the head, and the retinal vessels were beginning to be engorged. There was rather more swelling in the left ilio-costal space, and the skin of the lumbar region was slightly œdematous. The third and fourth lumbar spines were now

definitely tender, but not nearly so much so as the above-mentioned point two inches to the left of the middle line. The Babinski reflex was more marked. Owing to the mental condition it was impossible to satisfactorily test the sensation, and no paralysis or paresis of the legs could be discovered.

It was now felt that the combination of such extremely acute symptoms in the lumbar region, with signs of commencing meningeal infection, pointed to acute spinal osteomyelitis as being the most probable cause of trouble, and the very grave condition of the patient indicated that an exploratory operation should be undertaken without delay. It was thought advisable not to attempt a lumbar puncture on account of the risk of conveying infection into the theca if the needle should chance to pass through a collection of pus on its way into the spinal canal. Dr. G. A. Bannatyne, physician to the hospital, kindly saw the case in consultation, and strongly supported the view that a determined attempt should be made to find pus in connexion with the spine.

The situation of the swelling and of the most acute point of tenderness to the left of the spine, coupled with the comparative absence of tenderness over the spinous processes themselves, had led to the supposition that the disease had started in the bodies of the vertebræ, and that pus was tracking back between the tendons of origin of the psoas. A long vertical incision was therefore made over the outer border of the left erector spinæ; this muscle was pulled inwards, the posterior layer of the lumbar aponeurosis divided, and the finger insinuated between the psoas tendons to the front of the spinal column. Nothing abnormal was found and the wound was closed by deep and superficial sutures.

A second long incision was then made in the median line, and the left side of the lumbar laminæ was exposed. They appeared to be normal. An exploring needle was then introduced into the spinal canal between the third and fourth laminæ, when thick grey-green pus at once appeared in the syringe. The operation was then completed by the removal of the second, third, and fourth lumbar laminæ. The inner surface of the third lamina was black and necrosed, and the spinal canal was full of pus and lymph. The theca was carefully cleansed and the wound well washed with hot saline. There was no escape of cerebro-spinal fluid, and after removal of the pus the theca pulsated freely. A rubber tube was laid along the opened canal and the wound closed over it in layers by catgut sutures. The duration of the whole proceeding was 55 minutes and the boy was immensely relieved by it.

For six days afterwards convalescence was satisfactory, and then cerebro-spinal fluid began to flow freely from the wound. The patient did not appear much the worse for this, but a week later he had a severe secondary hæmorrhage, from which he nearly died. He was again put under anæsthesia, both wounds were opened up, cleansed, and packed with iodoform gauze. A hole could be seen in the theca from which cerebro-spinal fluid was running. An attempt to close it failed as the sutures cut out of the inflamed meninges. After this the boy made an uneventful recovery. The flow of cerebro-spinal fluid stopped in a week, and the wounds granulated up from the bottom. A small sinus was left for several months, but gradually closed. Two months after the operation slight knee-jerks were present and the Babinski reflex had disappeared.

The pus removed from the spinal canal was examined by Dr. Rupert Waterhouse, pathologist to the hospital, and found to contain staphylococcus aureus in pure culture.

Mr. Mumford informs us (November, 1911) that the boy is in good health, and that there is remarkably little weakness of the spine, though a poroplastic jacket is still worn as a matter of precaution.

From an examination of such of the literature as has been accessible to us, it appears that our case may be taken as a fairly typical instance of the most acute variety of spinal osteomyelitis. The disease is apparently not a very common one, but it has evidently so often been mistaken for other affections that it may perhaps not be so rare as is generally supposed.

For the short account of its general characters which follows we must express our indebtedness to the papers of Makins and Abbott, of Otto Hahn, and especially to the elaborate analysis of 68 recorded cases by Hunt in the *New York Medical Record* for 1904. A further list of papers on the subject is given below.

The subjects of the disease are generally under the age of 20, though occasionally it occurs in persons over middle age. What appears to be the first reported instance occurred in a man aged 63, whose case was described by Delafield at the Pathological Society of New York in 1875. In most instances there is a history of some slight injury such as a blow or strain, and sometimes some local cause of sepsis, such as furuncle, is present. The onset is accompanied by high fever and very severe local pain. In our case the extreme severity of the pain was such as to create an impression in our minds that we had never met with anything quite like it before. Rigidity and tenderness of the spine are usually present, sometimes retraction of the head, or opisthotonos. It is said that jarring of the spine does not produce pain as it does in Pott's disease, and this was so in our case.

Abdominal pain and distension are nearly always present, and may lead to much difficulty in distinguishing the disease from some acute abdominal condition. In a case reported to THE LANCET by Totherick in 1885, the abdominal symptoms were so marked that a surgeon was called in with a view to laparotomy. No operation was done, however, and the patient shortly afterwards died from pyæmia.

The nerve symptoms, when fully developed, are those of pressure on the cord at the segment affected—viz., root-pains with paralysis and exaggerated reflexes below. The paralysis has been known to spread rapidly upwards owing to burrowing of pus in the peri-dural cellular tissue, thus giving rise to a mistaken diagnosis of Landry's paralysis.

Unless early relief is given by operation, these cases rapidly go from bad to worse, and are characterised by continued high fever, rigors, splenic enlargement, formation of abscesses in situations varying according to the locality of the lesion, visceral complications, and pyæmia.

The disease has been mistaken for enteric fever, pneumonia, peritonitis, and acute spinal meningitis, and considering the varied and puzzling character of the symptoms which may arise in its course, this is not to be wondered at.

The outlook is always grave, the mortality being estimated by different writers at from 60 to 75 per cent. It is obvious that the only possible chance of recovery must lie in early diagnosis and prompt operation.

LEAD BULLET REMOVED FROM METATARSAL BONE AFTER 23 YEARS.

BY J. B. CHRISTOPHERSON, M.D. CANTAB., M.R.C.P. LOND., F.R.C.S. ENG.,

DIRECTOR OF HOSPITALS, KHARTOUM AND OMDURMAN; SURGEON, KHARTOUM HOSPITAL, ETC.

IN THE LANCET of Oct. 1st, 1910, p. 1010, I reported a case of the removal of a bullet 11 years after the battle of Omdurman, where it was received. On March 16th, 1911, I removed at the Khartoum Civil Hospital, after 23 years, a leaden bullet from the fourth metatarsal bone of the left foot of a Jaalin Arab, aged about 45, who had received it in 1888 at Handub, near Suakim, in a small engagement when Colonel Kitchener (Lord K.) attacked Osman Digna with partial success.

The only symptom the man complained of was that when he put on his putties the foot swelled. There was no pain, although his principal occupation is walking and carrying messages about Khartoum. There was the story of the bullet wound of the foot, with two months' incapacity afterwards, with discharge of pus and blood. Afterwards he noticed

nothing until a fortnight previous to applying to hospital, when, I presume, the slightly increased pressure in the veins by the putties caused some little swelling or a feeling of tightness in the foot.

On examination the fourth toe looked shorter, and there was some thickening of the shaft and base of the fourth metatarsal bone. The wound of entrance was represented by a scar on the dorsum of the foot. As the man said that he had seen the bullet and had held it in his hand, and was certain that it came out again, I was rather surprised to see the indications of a foreign body present on the X ray plate—a print of which I send, and which was kindly taken by Major Carroll at the Egyptian Army Hospital at Khartoum.

Skiagram showing position of bullet.

On cutting down on the bullet a leaden ball of the circumference of a thumb-nail was completely covered with bone on all sides, and was situated near the base of the bone. On gouging through the osseous tissue I came across tiny specks, or particles, of lead, more numerous the nearer the bullet was approached, as if the bullet on reaching its destination had splashed fragments of lead all round, the splashes being fainter the farther away from the bullet. The bullet was contained in a round smooth cavity, lined like the smooth porcelain surface of an osteo-arthritic joint, and resembling a diminutive acetabulum after the bullet was extracted. It showed no signs of erosion and fitted tightly into its bony cavity.

The bullet had evidently fractured the bone and lay amongst the fragments, and had become encysted amongst the osseous fragments when the bone healed up, and had remained quiescent for 23 years, neither eroding the bone nor being acted on by the tissues or fluids of the body. Finally, the bullet was a round lead bullet about the circumference of an adult thumb-nail, probably from a gun of an old type (? a muzzle-loader).

Remarks.—I do not know of a reported case of a bullet being removed after 23 years. It had caused the man no trouble practically for 23 years, and had not interfered with his occupation, although it was embedded in his foot, and his occupation involved much walking about. It was firmly encysted in the bone, and I do not think that more inconvenience was caused by its presence than if it had not been there at all, nor was there any greater disturbance of the surrounding tissues than the original fracture of the bone itself would account for.

Finally, I do not think a foreign body becomes, as a rule, absorbed by the tissues or tissue fluids of the body when embedded in them, nor does it tend to move about unless it is alive, like a guinea-worm, or infected by micro-organisms; nor will it, as a rule, by its mere presence cause any harm at all, and this is, I think, contrary to the usual teaching.

Khartoum.

THE LYMPHATICS OF THE SCROTUM

IN RELATION TO THE RADICAL OPERATION FOR SCROTAL EPITHELIOMA.

BY JOHN MORLEY, CH.M. MANCH., F.R.C.S. ENG.,
TOM JONES SURGICAL SCHOLAR; DEMONSTRATOR OF ANATOMY, MANCHESTER UNIVERSITY.

THE investigations that follow were undertaken under the conditions of tenure of the Tom Jones Surgical Scholarship of Manchester University.

I became convinced of the need for this work by the following considerations. In the first place, my experience of surgical practice in the Manchester Royal Infirmary during the past few years led me to believe that epithelioma of the scrotum is, in Lancashire at any rate, by no means so rare a disease as is generally supposed, and that glandular metastasis is, on the whole, neither late nor unusual. The frequency of the disease has been definitely established, however, by the work (at present unpublished) of Mr. S. R. Wilson, who, in the course of an etiological investigation into epithelioma of the scrotum, has collected a series of 40 cases from the records of the Manchester Royal Infirmary and the Christie Cancer Hospital during the past ten years.

I find that in the five years 1906–10 inclusive 30 cases of scrotal epithelioma were admitted to the Manchester Royal Infirmary, an average of six per annum, and it is worth noticing that during the same period there were admitted only 25 cases of epithelioma of the penis.

Secondly, the disease receives very meagre treatment in most of the surgical text-books, and in the chief works on operative surgery is not even mentioned. Further, the description of the scrotal lymphatics in the various anatomical text-books, of which the best is found in Poirier et Charpy (Tome II., Fasc. 4), did not appear to me so complete as the practical importance of the region demanded.

I have approached the subject from a frankly surgical point of view, with the object of attempting to place the operation for radical cure of cancer of the scrotum on as sound an anatomical basis as that for malignant disease of the breast.

With this object I have set myself to elucidate the following questions:—

1. The arrangement of the lymphatic vessels draining the scrotum and the collecting trunks into which they lead.
2. A more precise knowledge of the topography of the inguinal glands into which they drain.
3. Do any of the scrotal lymphatic trunks pass by the inguinal glands without entering them, and go primarily to the intrapelvic glands along the external iliac artery?
4. The effect of age upon the condition of the scrotal lymphatic drainage apparatus, and more particularly its condition in the age of greatest predisposition to cancer.

Classification of the Superficial Inguinal Glands.

The conventional text-book and clinical division of these glands is into (1) a superior or oblique set, just below and parallel to Poupart's ligament, with which their long axes are also parallel; and (2) an inferior or vertical set, grouped round the upper two inches or so of the internal saphenous vein, and elongated in a vertical direction.

The first group is described usually as receiving the lymphatics from the lower trunk, gluteal and perineal regions, and from the skin of the external genitals; the second, as receiving most of the superficial lymphatics of the lower limb. This classification has been accepted generally on account of its simplicity and its rough and ready accuracy.

I venture to think, however, as has been pointed out by Poirier, that it is an inadequate classification. In the first place, there are a number of glands, round or irregular in shape, which lie round the sapheno-femoral junction, which cannot be assigned definitely to either group by dissection. Secondly, injection experiments entirely fail to show any such simple arrangement of the afferent vessels as that usually described. This is borne out by clinical work, for it must have fallen to the lot of every surgeon to see some glands of the vertical chain infected from a primary lesion of the genitals, or some of the upper oblique set of glands involved in septic conditions of the foot.

There is, in fact, no possibility of a perfectly clear natural classification of these glands, so variable are they in their arrangement and drainage areas. Since, however, some classification of so large a group is imperative from the surgical standpoint, I have adopted the clear but arbitrary division of Poirier, following Quénu. He draws two imaginary straight lines, one vertical, the other horizontal, which meet at the junction of the saphenous with the femoral vein. We thus get four groups of glands—viz., supero-external, supero-internal, infero-external, and infero-internal (see figure). It will be observed that the lower part of our imaginary vertical line corresponds roughly with the internal saphenous vein, which is the surgeon's most important landmark in the subcutaneous tissue of this region. I have not adopted Poirier's fifth or central group of glands, lying over the saphenous opening, as this brings an unnecessary complication into our artificial classification.

Technique.

I have worked exclusively with Gerota's fluid (a suspension of Prussian blue in turpentine and ether), and my injections have been made by means of a mercurial constant pressure apparatus prepared from the specifications of Professor J. K. Jamieson of Leeds, and described by him and Mr. J. F. Dobson.[1] The finest hypodermic needles were used. A pressure of 10–15 cm. Hg was found the most useful.

Successful injections were made in the bodies of four stillborn infants and 13 adult males. The latter were found the more satisfactory to work with, especially if emaciated. In the case of the stillborn infants the injections were made within a day of birth, and the subjects were hardened in 10 per cent. formalin before dissection, but the adults were injected 5–6 days post mortem when rigor mortis had passed off. They were then preserved by the usual formalin injection, and the arteries were finally injected with starch and vermilion. The somewhat laborious dissections of the lymphatics were completed after this.

Results.—Influence of Age.

The lymphatics of the scrotum are remarkably well developed at all ages. The fœtal vessels are easier to inject, but more difficult to dissect out on account of their minuteness and the abundance of fat in the groin.

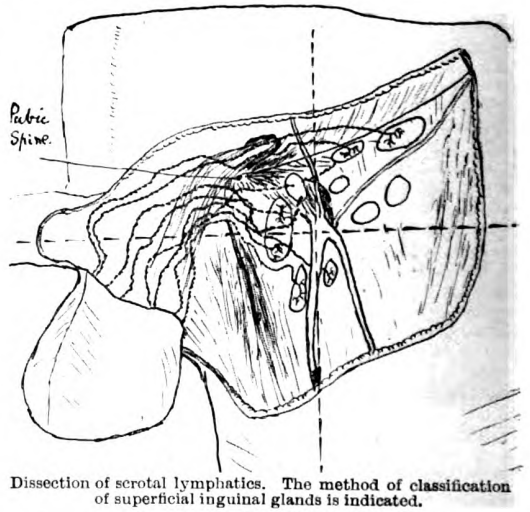
The 13 adult bodies injected varied from 36 to 80 years of age, and the majority were over 50. I found after some practice that I could invariably obtain a successful injection, and that old age brought no perceptible diminution in the number and calibre of the lymphatic vessels. The size and number of the inguinal glands varied considerably in different subjects, but some of the oldest bodies possessed uncommonly large glands.

Microscopical sections of glands taken from a series of six subjects aged from 70 upwards showed, however, marked age changes when compared with fœtal glands. The central medullary portion of the gland becomes entirely replaced by fibrous tissue. Some cases show extensive fatty degeneration. The fibrous capsule is also greatly thickened, and only in the attenuated cortical zone does lymphoid tissue remain. Such of the lymphoid tissue as remained appeared, however, quite normal in structure, and the peripheral lymph sinus was quite evident in all.

[1] Journal of Anatomy and Physiology, October, 1910.

Network of Origin.

In the deeper layers of the cutis vera and superficial to the dartos muscle is a very rich and fine network of lymphatic capillaries. The blue injection can be seen through the delicate scrotal skin shooting out in all directions from the point of the needle into this network. By a single puncture one can often obtain an injection of practically the whole of the scrotum and penis.



It should be noted particularly: (1) That there is a free communication by means of this network between the lymphatics of the two sides of the scrotum, across the raphe; and (2) that there is an equally free communication with the superficial network of lymphatic capillaries in the skin of the penis. The network also spreads into the skin of the thighs and perineum, but here it becomes much less highly developed.

Collecting Trunks.

Taking origin from this delicate superficial network, one can see numerous collecting trunks of considerable calibre. They dip down at their origin through the dartos muscle and run in the subcutaneous tissue for the rest of their course to the glands. The thick blue lines of the injected trunks can be seen through the thin scrotal skin and dartos without any dissection, but as soon as they reach the groin, where the subcutaneous fat begins, they are hidden from view until dissected out.

From 10 to 15 collecting trunks leave the scrotum on each side. They show, when distended, a characteristic beaded appearance due to the very numerous valves, and vary considerably in thickness in different bodies. The thickest trunk that I have observed had a diameter at its most distended part, above a valve, of 2 mm., but the average maximum diameter is from 0·5 to 1 mm. The course of the trunks is tortuous, as might be expected in so mobile a region, and they cross one another and anastomose to some extent.

It is necessary for purposes of description to classify these trunks arbitrarily into three groups—viz., anterior, lateral, and posterior, according to the region of the scrotum from which they take origin.

Dissection of scrotal lymphatics. The method of classification of superficial inguinal glands is indicated.

Anterior trunks (see figure).—These are of chief importance, since epithelioma usually commences on this aspect of the scrotum. Further, the long and peculiar course of the medial trunks has not been accurately described, as far as I can ascertain, by other workers.

(*a*) The medial trunks, 2–3 in number, run up the anterior surface of the scrotum parallel and close to the raphe until they reach the root of the penis. Here, instead of turning

outwards at once, they mount up on to the lateral aspect of the penis, the highest and most medially placed trunk reaching a point on the side of that organ varying from 1 to 2·5 cm. from its root. Curving down on the dorso-lateral aspect of the penis they gain its root, pass outwards and slightly upwards into the subcutaneous fat of the abdominal wall about 1 cm. above the pubic spine, run at first parallel to and above Poupart's ligament, and then turning down and crossing it obliquely end, as a rule, in a gland of the supero-external group which lies just below Poupart's ligament with which its long axis is parallel.

This gland always lies definitely to the outer side of the line of the saphenous vein, and may be within 4 cm. of the anterior superior spine. In their course to this gland the vessels pass sometimes between the superficial epigastric vein and the skin, sometimes underneath it. It often happens that the lower of these trunks curves down from the region of the pubic spine, and ends in one of the supero-internal glands, leaving only a single trunk to take the long course described above.

(*b*) The *outer trunks* from the anterior surface, three or four in number, do not run upwards parallel with the raphe, but pass upwards and outwards, and gain the anterior aspect of the spermatic cord. At or a short distance below the level of the pubic spine they curve first outwards and then slightly downwards, and end, after various anastomoses, in glands of the supero-internal and infero-internal group.

Lateral trunks.—These are four or five in number. They run upwards on the lateral aspect of the scrotum and spermatic cord, and curve outwards 1–2 cm. below the pubic spine, to reach the supero-internal and infero-internal glands. Sometimes a trunk runs underneath the saphenous vein, just below its junction with the femoral vein, and ends in an infero-external gland.

Posterior trunks.—On each side of the raphe, and about 0·5 cm. from it, a large collecting trunk runs upwards from the most dependent part of the scrotum towards the perineo-scrotal junction. Into this trunk run four or five tributaries, which pass transversely across the posterior surface of the corresponding side of the scrotum from without inwards. The main trunk turns outwards a short distance below the junction of scrotum and perineum, runs at first upwards on the posterior aspect of the spermatic cord, and then turning outwards into the thigh about 2·5 cm. below the pubic spine ends in a gland of the infero-internal group, lying parallel with the saphenous vein about 2–4 cm. below the sapheno-femoral junction.

No collecting trunks accompany the perineal and internal pudic vessels into the pelvis.

In one subject I observed three or four trunks originating in the lower part of the anterior surface of the scrotum, which ran backwards through the lower part of the scrotal septum to end in the main posterior trunk. I have not been able to demonstrate this arrangement in other subjects.

The efferent trunks from the superficial inguinal glands sometimes run to other glands of the same group, and sometimes they join a gland of the deep femoral chain. Most of them, however, converge on two or three large thick-walled trunks which, after piercing the cribriform fascia, run up through the crural canal to the inner side of the femoral vein, and end in glands lying along the inner or pelvic side of the external iliac vessels.

I have never been able to find a trunk that passed by the inguinal glands and primarily entered the intrapelvic glands. There does not appear to be any communication between the superficial lymphatics and those of the tunica vaginalis and testis.

Practical Conclusions.

1. In consequence of the very free anastomosis between the superficial lymphatic network of opposite sides, it is obvious that whenever an epithelioma approaches the median raphe the glands of both groins must be removed.

2. In view of the termination of the medial trunks from the anterior surface in the supero-external glands, it is important that, when a growth approaches the anterior raphe, the subcutaneous tissue and glands should be removed to within one inch of the anterior superior spine of the ilium. I have seen recently a case in which a very determined attempt at a radical operation failed because the surgeon had not carried his dissection far enough in an outward direction (see figure). Recurrence took place within nine weeks of the operation in the extreme outer angle of the incision.

3. It is essential to remove the superficial inguinal glands and subcutaneous tissue in which they lie, from practically the whole of Scarpa's triangle, and to carry the upper limit of the dissection well above the inner half of Poupart's ligament. To clear the triangle efficiently the upper three inches (7·5 cm.) of the internal saphenous vein must be excised and the femoral sheath stripped clean.

In view of Handley's work on permeation of lymphatics and the protective process of peri-lymphatic fibrosis in cancer of the breast, it is scarcely possible, without further histological investigation, to dogmatise on the necessity of removing all the intervening lymphatic vessels, in addition to primary growth and glands.

It is certain that secondary malignant growths are, in this region, extremely rare in the course of the lymphatic trunks, as compared with growths in the glands; and it may prove that the vulnerability of the vessels is so slight as not to warrant the additional mutilation involved in their complete extirpation.

Many surgeons, however, will consider it their duty to aim at the ideal of complete removal of all possible malignant cells, here as elsewhere, and attention to the above description should provide the necessary anatomical data for an early case. It will rarely be possible after such an operation to bring the skin completely together. As far as the necessarily denuded root of the penis is concerned, it will be possible to cover it in the uncircumcised by incising the prepuce on the dorsum (if there should be a tendency to phimosis), and utilising the additional skin gained by its retraction. Apart from this, skin grafting would be required.

Manchester.

THE SYSTOLIC BLOOD PRESSURE IN DISEASES OF THE HEART.

BY VISHNU T. KORKE, M.R.C.P. EDIN., D.T.M. LIVERP., L.M. & S. BOMBAY,

LATE ASSISTANT RESIDENT MEDICAL OFFICER, BARNES CONVALESCENT HOSPITAL OF THE MANCHESTER ROYAL INFIRMARY; JOHNSTON COLONIAL FELLOW IN THE UNIVERSITY OF LIVERPOOL.

THE observations recorded in this paper were made on patients suffering from: (1) simple, uncomplicated valvular lesions of the heart due to acute rheumatic endocarditis; (2) valvular lesions due to other causes; and (3) other heart affections. No systemic complications were observed in cases of valvular lesions due to rheumatic endocarditis. There were no cyanosis, dyspnœa, changes in the fundus oculi, febrile temperature, and albuminuria, though traces of albumin were sometimes detected in a few cases. The observations were made on patients of both sexes, of different ages, sent to the Convalescent Hospital from the Manchester Royal Infirmary. They were allowed a mild out-door exercise, and generally they were keeping in good health.

The apparatus used for the observations was a sphygmomanometer, a Martin's modification of Riva-Rocci. The systolic blood pressure was recorded by the armlet method during the recumbent posture of the patients. The observations were made daily, under similar circumstances, nearly an hour before dinner (at 1 P.M.), and in cases of doubt they were repeated two to three hours after 8 P.M. A record of pulse-rate and number of respirations was kept during the observations, and sphygmographic tracings of the pulse were often made to note the effect of blood pressure on the pulse. For the convenience of this article only the number of observations and the mean blood pressure are recorded.

The conclusions were arrived at by consulting the following table[1]:—

Age.	Normal systolic blood pressure.
Children and adolescents	90 mm. Hg.
Young and middle aged (35–45 years)	115–125 mm. Hg (mean 120).
Over 45 and elderly	135–145 mm. Hg (mean 140).

In women 5 to 10 per cent. less than the above figures.

I.—In valvular lesions of the heart (with or without complications), due to rheumatic endocarditis and other causes, the blood pressure was found to be normal or above normal.

II.—In simple and uncomplicated valvular lesions of the heart, due to acute rheumatic endocarditis, the blood pressure was found always to be normal or above normal. These results agree with those arrived at by Starling.[2]

III.—In aortic incompetence complicated with anginal attacks, the blood pressure was found to be *subnormal* during the interparoxysmal periods. The low systolic blood pressure is, perhaps, an expression of the failing power of the myocardium.

IV.—Significance of high blood pressure in simple and uncomplicated valvular lesions of the heart due to rheumatic endocarditis. The high blood pressure observed in some of the cases is, I believe, a physiological compensation in those individuals, though it may be mistaken for a pathological state. As is well understood, the normal blood pressure is maintained by the coördination of the three factors—viz., (1) Rhythmic and forcible contraction of the myocardium; (2) tonic action of the arterial walls; and (3) contraction of the arterioles. In valvular diseases of the heart the defective normal action of the myocardium must be corrected, first, by making a demand on its reserve power; secondly, by supplying a proper amount of blood under the altered circumstances, thereby maintaining a new blood-pressure level. Vaso-constriction is the first effort made to correct the myocardial insufficiency by inciting the ventricles to restore the proper output to its previous amount (Starling).[3] Consequently the height of blood pressure may vary according to the degree of vaso-constriction, and condition and demand of the myocardium.

For such patients, therefore, who showed no complications and who were comparatively active and comfortable, an average level of arterial blood pressure *even above normal* was absolutely necessary to ensure the requisite speed of capillary blood flow.[4] In such cases the high blood pressure was not incompatible with average normal health.

V.—The blood pressure in cardiac muscle failure was normal or well above normal. I believe that the high blood pressure in cardiac muscle failure was due to various pathological causes which produced a change in the myocardium. It was pathological in nature.

VI.—In valvular lesions, complicated with chronic nephritis and arterio-sclerosis, the significance of supernormal blood pressure requires no comment. It is distinctly pathological.

UNIVERSITY COLLEGE HOSPITAL.—Captain the Honourable Edward Stanley Dawson, R.N., has accepted the appointment of chairman of the Corporation of University College Hospital in succession to the late Earl Cathcart.

THE SPECIFIC GRAVITY OF THE BLOOD FROM THE CLINICAL ASPECT.

BY ATHOLE ROSS, M.D. CANTAB., M.R.C.P. LOND.,
PATHOLOGIST TO THE EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL, E.

I WAS recently asked by the late Dr. J. A. Coutts to assist Major Leonard Rogers, I.M.S., in the preparation of a number of glycerine-water solutions for taking the specific gravity of the blood; these were required for use in connexion with the treatment of epidemic enteritis by hypertonic salines and permanganates, on similar lines to the new methods of dealing with cholera recently introduced by Major Rogers and his co-workers at Calcutta. There are three methods of determining blood specific gravity:—

1. Hammerschlag employed a mixture of chloroform and benzol having a specific gravity between 1055 and 1060. A drop of blood is allowed to fall into this mixture from a pipette. If the blood floats benzol must be added and the solution stirred; if it sinks the addition of chloroform is required. When the drop floats suspended a urinometer is used to take the specific gravity of the mixture. Criticising this method Major Rogers observes that the smell of the mixture is objectionable, and quotes Da Costa for the statement that an ordinary hydrometer gives a reading exceeding the correct figure by from 3 to 10 degrees. What Da Costa exactly means by this is a little difficult to see, for if the hydrometer gives untrustworthy readings all the observations must be valueless. A great disadvantage of the method is the time it would consume when a dozen or so of determinations have to be made during the morning round; it also requires some manipulative skill, as the drop of blood is liable to break up in the mixture.

2. In Schmaltz's method the weight of equal quantities of blood and water are obtained by previously weighing a perfectly clean dry pipette and then filling it. The accuracy of this method is only limited by the technical ability of the observer and the sensitiveness of his balance. It is, however, quite unsuited for clinical purposes.

3. The remaining method is to make up a large number of glycerine-water solutions[1] whose specific gravities "should represent every other degree from 1040 to 1076." (Rogers.)

It would appear that the glycerine and water solution was used by some in precisely the same way as Hammerschlag's mixture of benzol and chloroform; for Dr. J. H. Drysdale, in the latest edition of "Allbutt's System of Medicine" (Vol. I., p. 650), writes: "In Roy's method, of which Hammerschlag's is a modification, the fluid employed was a mixture of water and glycerine. In both the principle is the same, and the method has been largely used in this country by Drs. Copeman and Lloyd Jones." Now Major Rogers, and presumably also Dr. Lloyd Jones quoted by him, makes use not of a single solution of about the specific gravity which it is expected the specimen of blood will be, but of a whole series of solutions of glycerine and water extending from specific gravity 1040 to specific gravity 1076. I am here concerned with a means of rapidly and easily preparing these solutions.

When Major Rogers made up the mixtures in my laboratory he simply mixed the water and glycerine in the rough proportions that he knew from experience would be wanted, and then by adding either water or glycerine, while testing with the hydrometer, obtained the various solutions. This method is rather uncertain except in experienced hands, and it is, moreover, decidedly tedious and lengthy. Major Rogers admitted that even he on occasion had had some trouble with this procedure. It is merely a matter of calculation to find how much glycerine of specific gravity 1·26 must be added to 500 c.c. of distilled water so that the resulting specific gravity of the mixture may be 1056 (about that of normal blood); 137·2 c.c. of glycerine are required. A table was constructed giving the calculated amounts of glycerine to be added to 500 c.c. of water in order to obtain mixtures of specific gravities 1036, 1038 to 1072, 1074 inclusive. On experimenting with certain of the calculated quantities it was found that the specific gravities of the solutions obtained were a few degrees out, either in excess or defect of what they should be. Having ascertained that by law the specific gravity of a sample of pure glycerine must be 1·26, I thought that, as glycerine was hygroscopic, some contraction in the total volume of the mixture must occur to account for the error found, and that also a correction could be applied to allow for this. On looking into the matter it became apparent that although glycerine is commercially sold as 1·26, it very frequently has a specific gravity of 1·265. Taking the gravity of glycerine 1·265 the quantity of glycerine required for the experiment above detailed would be 134 instead of 137·2 c.c. The full table was then abandoned and the following four solutions retained to form a basis for the preparation of the entire series. Taking the specific gravity of glycerine as 1·265, the result obtained was as follows:—

Distilled water.	Glycerine. Sp. gr. 1·265.	Sp. gr. of mixture—	
		As calculated theoretically.	As found by experiment.
A. 500 c.c.	88·9 c.c.	1040	1043
B. 500 c.c.	116·3 c.c.	1050	1055
C. 500 c.c.	146·3 c.c.	1060	1065
D. 500 c.c.	179·5 c.c.	1070	1075

The best way to use this table is to prepare from it four working solutions, A, B, C, D, and these may be each 500 c.c. (or better a litre) of distilled water plus the requisite quantity of glycerine.

Example.—Having made solution B, the addition of a small quantity of glycerine, while stirring and testing with the hydrometer, will bring the gravity to 1056. Of this 1056 mixture 200 c.c. are set aside; then by the addition of a further quantity of glycerine 1058 and 1060 are obtained—portions set aside for stock, and next by adding water to the remainder 1054 and 1052 are worked out. Afterwards Solution A is taken to make 1038 to 1050, and so on till all the 20 solutions required are prepared.

Some tall glass vessels 2 inches to 2½ inches in diameter are required, together with 100 c.c. measures and an accurate hydrometer. It is to be noted that although the exact specific gravities of the solutions obtained by adding the measured quantities of glycerine to the constant volume of distilled water will vary a little (and experiment will not quite agree with theory), we may be certain of getting *four working solutions whose specific gravities will lie within the limits of the series of mixtures that are required.* From them the whole series from 1036 to 1076 can readily be prepared. The small discrepancy between a specific gravity as calculated and one as found is due to the fact that, although the specific gravity of a trustworthy sample of pure glycerine must be 1·26, there is no relying on what the figure in the third decimal place will be. Evidently the specific gravity of the glycerine I employed was neither 1·260 nor 1·265. A large bore burette will be found useful for making small adjustments in the quantities of glycerine added. A crystal of thymol should be placed in each stock bottle as a preservative.

The best method of using the solutions clinically is outlined in Dr. Rogers's book. A series of small glass-stoppered testing bottles is put up, labelled, and boxed in numerical order.[2] A drop of blood is drawn up in a capillary pipette, fitted with a rubber cap, and gently expelled into the bottles in turn till one is found in which it just floats suspended, or, breaking up slowly, rises and falls at the same time: this bottle gives the required specific gravity. If it is found, for example, that the drop rises slowly in 1052 and sinks slowly in 1050 the specific gravity is intermediate—viz., 1051. The best way to obtain the blood in children is by placing a ligature round the big toe. I found in my own case that it makes no difference to the reading whether the blood is obtained from the thumb in this way or from the lobe of the ear without pressure.

From the few observations I have made I am inclined to think that the blood specific gravity in children is more variable than in adults, and that it is harder to fix a normal for them. The specific gravity certainly rules lower; and the test bottles at the higher end of the series are seldom

[1] I use the term "solution" in this paper when strictly "mixture" should be employed.

[2] The mixtures in these should be renewed from stock as soon as they become turbid and discoloured.

required, even when the blood has become concentrated by severe diarrhœa. I am rather doubtful if the blood specific gravity will prove so important a guide in the treatment of epidemic enteritis by the Rogers method as it appears to be in the case of cholera. Probably those who now working in the wards at Shadwell will soon be able to settle this question.

It is an undeniable fact that usually the specific gravity of the blood has not much importance from the clinical point of view, and it was only when asked to assist Major Rogers that my attention was directed to devising a means whereby the labour of making up so many glycerine-water mixtures to a prescribed degree of specific gravity might be lightened. No one, however, can read Major Rogers's book on cholera without being impressed by the important part which the determination of the blood specific gravity plays in his system of treatment, and it may well be that this is one of those exceptions which go far to prove the rule. That a parallelism exists between the specific gravity of the blood and the hæmoglobin content of the red cells is well known, and both Hammerschlag and Schmaltz have constructed tables showing the percentage of hæmoglobin, corresponding to different degrees of specific gravity. The suggestion has been made that the hæmoglobin content could be deduced from a determination of the specific gravity of a sample of blood, but the changes in the plasma in severe anæmia, leukæmia, dropsy, and diarrhœal disease render this practice unreliable. In conclusion, I have to thank Mr. Elms for independently confirming the figures given in the table.

Shadwell, E.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES ON A CASE OF GASTRO-ENTEROSTOMY.

BY PENROSE WILLIAMS, F.R.C.S. EDIN.,
HONORARY SURGEON TO THE BRIDGWATER HOSPITAL.

THE fact of a suture remaining dormant for three years and then being extruded in the happy manner described below is, I believe, unusual, and therefore the case seems worth recording.

The patient, a female, aged 32 years, was admitted to hospital in June, 1907, with a history of 17 years' ill-health. She had a sallow, muddy complexion, looked thin and badly nourished, complained of more or less continuous indigestion and constipation, and stated that she had been under medical treatment off and on for many years. There was no dilatation of the stomach or any other abnormal physical condition discoverable. I advised exploration with a view to gastro-enterostomy.

The operation was performed on June 6th, the abdomen being opened by a vertical incision above and to the left of the umbilicus and lateral dislocation of the left rectus muscle. A chronic ulcer was found near the lesser curvature and pylorus. This was left alone and a posterior gastro-enterostomy performed. The points especially observed were: (1) to take the highest possible part of the jejunum; (2) to make the incision in the stomach wall reach the greater curvature; and (3) to fix the margins of the opening in the meso-colon to the jejunum below the anastomosis by three points of suture, one anterior and two lateral, the whole line of suture being thus occluded within the lesser sac. Two continuous sutures of fine silk were used for the anastomosis in the usual way.

Recovery was uneventful and the patient was sent to the Weston Convalescent Home on July 22nd, returning from there a month later for inspection. She had gained considerably in weight, was in very good health, and immediately resumed her work as a domestic nurse, remaining at it in excellent health for nearly three years.

In June, 1910, the patient reported that she had noticed a gradually increasing swelling in her "stomach" for a few weeks, but that it caused her no inconvenience. On examination there appeared a globular fluctuating swelling, of the size of a large orange, presenting just above and to the left of the umbilicus. The swelling was below the stomach and fixed to the anterior abdominal wall, but was quite free of the operation scar, which was scarcely visible. She was readmitted and the swelling was carefully incised under general anæsthesia, and without opening the general peritoneal cavity. About half a pint of pus, free from smell, came away. Gentle digital exploration of the cavity did not reveal its relation to the transverse colon, and extensive manipulation being obviously undesirable, this point was not determined. A large drainage-tube was put in, and the outcome was awaited. Three days later a piece of silk, 7½ in. long, came away in the discharge. The wound then rapidly healed. The patient soon returned to work again, and has remained quite well.

This case is a fortunate example of the true function of a "foreign body" abscess—a collection of fluid formed for the twofold purpose of boring a way to the surface and floating out the offending substance. It also confirms the view that silk is an unnecessarily permanent material for internal suturing.

Bridgwater.

NOTES ON A CASE OF HEAT-STROKE OF THE HYPERPYREXIAL TYPE.

BY MARY A. BLAIR, M.D., B.S. LOND., B.SC. N.Z.

A WOMAN, aged 54, an inmate of St. Pancras Workhouse, was seen by me on the morning of July 22nd last, complaining of slight malaise. During the day she did her usual work in the kitchen of the workhouse, but she complained of thirst and was observed to be drinking large quantities of water. The temperature of the kitchen is reported to have been 91° F. About 6 P.M., while sitting on a bench in the workhouse yard, she was taken suddenly ill and was removed to the receiving ward.

On arrival there the woman was found to be very pale, with lips blanched, and the veins of the neck engorged. She was breathing without difficulty and her pulse was 100 and of good quality. She spoke a few words intelligently and then became incoherent, and afterwards restless and irritable, violently resisting examination. Her jaws were tightly clenched. Her pupils were at first slightly dilated, but in a few minutes they contracted, and complete unconsciousness supervened. The motions were passed under her. They were yellow and semi-fluid. Her skin felt very hot, and the temperature, taken in the axilla, was found to be 108°. Convulsive movements then began in the lower limbs and spread to the rest of the body. There were constant champing movements of the jaws throughout the attack.

Some cold sponging was done and the patient was removed to the ward. The whole body was then sponged with ice-cold water, but the temperature (taken in the rectum) remained at 105°. The patient was then covered with wet lint on which pieces of ice were placed, and finally the trunk and limbs were rubbed with pieces of ice. By 9 P.M. the temperature had fallen to 101·6°; the ice applications were discontinued and the patient was covered with a sheet. There was no vomiting, but several loose motions were passed. The convulsions continued, beginning sometimes in one or both arms and sometimes in the legs and spreading to the trunk. Movements of the jaws went on constantly. At 9 P.M. the convulsions became very severe, the limbs contracting so violently that it required several nurses to keep the patient on the bed. The pulse and respirations remained good. Chloroform was now begun and continued to full surgical anæsthesia before the movements could be controlled. With lighter anæsthesia the movements returned. The temperature rose again to 104·4°, but then fell steadily, no further sponging being given. At 1 A.M. the administration of chloroform was discontinued and the patient was watched for an hour, during which there was no return of convulsive movements, and the temperature continued to fall. At 8 A.M. she suddenly recovered consciousness, as if waking from sleep. She remembered nothing since being in the workhouse the previous afternoon.

Throughout the attack the patient suffered from hyperpyrexia and convulsions alone. The pulse remained strong and only slightly increased in rate, and the respirations were unaffected.

Recovery has been complete. No sequelæ have been

observed except occasional slight headaches, more noticeable on hot days, and slight vomiting on two occasions.

Vicarage-gardens, Campden-hill, W.

NOTES ON A CASE OF UTERINE FIBROID CAUSING GANGRENE OF THE LOWER LIMB.

BY F. S. CREAN, L.R.C.P. & S. IREL.,
ASSISTANT MEDICAL OFFICER, BERMONDSEY INFIRMARY.

I RECENTLY admitted to Bermondsey Infirmary a woman, aged 42 years, whose right foot showed signs of dry gangrene. At the time of admission the discolouration and anæsthesia extended from the toes to about the mid-tarsal joint. No definite history of injury could be obtained. The urine was carefully examined, but no abnormal constituent was found. She gave a history of rheumatism in childhood, and auscultation revealed the existence of a systolic mitral bruit. There was no evidence of failing compensation nor of pronounced arterial degeneration. As she was disinclined for a pelvic examination none was made. She stated that her menses were still regular. She was a multiparous woman whose last child was born several years ago.

Conservative methods and tonic treatment were tried for four days, but as the gangrene steadily spread along the foot and over the ankle amputation through the knee-joint was done on the fifth day after admission. On the day following the operation the patient's condition was very low, and a large purpuric-looking spot was observed over the right side of the sacrum. On the next morning the edges of the amputation flaps showed purple discolouration. The patient failed to respond to stimulant treatment, grew progressively weaker, while the vitality of the stump grew feebler, and on the fourth day after operation death occurred.

At the necropsy a large subperitoneal fibroid growing from the fundus uteri was found, pressing upon and almost entirely occluding the right external iliac artery.

Lower-road, Rotherhithe, S.E.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

MEDICAL SECTION.

Influence of Certain Accessory Food-stuffs (Tea, Coffee, &c.) on Gastric Secretion.—Association of Hysteria with Malingering.

A MEETING of this section was held on Nov. 28th, Dr. FREDERICK TAYLOR, the President, being in the chair.

Dr. F. CRAVEN MOORE and Dr. H. E. ALLANSON communicated a paper on the Influence of Certain Accessory Food-stuffs on Gastric Secretion. They said: The observations of Pawlow and his co-workers having established the varying influence of different dietetic substances on the rate of gastric secretion and the activity of the secreted juice in the dog, it was accepted as at least highly probable that a similar relation would obtain in the human subject, and in a limited fashion the truth of this has already been established. In view of these results it appeared to us that it would not only be of interest, but of some practical importance, to determine by observation on the human subject the varying effect on gastric secretion of certain food-stuffs, essential and accessory, which by their use or interdiction in disorders of gastric activity have been credited empirically with having some particular relation, ameliorative or causal, with such disorders. The substances so far included in our investigations are: water, tea, coffee, cocoa, milk, albumin water, meat extracts, and alcohol; in addition a few observations have been made on the effect of tobacco-smoking. The methods employed consisted in the administration on the empty fasting stomach, at 8 A.M., of a test-breakfast composed of four "breakfast biscuits" and 10 oz. of fluid, either water or freshly infused tea, coffee, or cocoa without milk or sugar, or milk, or albumin water containing the white of one egg in 10 oz. of water, or two teaspoonfuls of meat extract in 10 oz. of water, or 2 oz. of whisky with 8 oz. of water. The fluid was heated to an agreeable temperature. The stomach contents, removed one hour later, were immediately filtered, and in the filtrate the free hydrochloric acid and the total acidity were estimated by titration with decinormal soda solution, dimethylamidoazobenzol and phenol-phthalein, respectively, being used as indicators; the peptic activity was estimated according to the Edestin method of Fuld and Levison. The results obtained with the test-breakfast consisting of four biscuits and 10 oz. of water were made the basis for comparison throughout the observations, and in each individual case the measure of the secretory reactivity to water and to the particular substance under investigation was determined on the average of not less than three experiments with each. The 15 individuals on whom the observations were made included normal healthy subjects, and subjects both with and without definite gastric disorder. The results as expressed in the accompanying table are the averages of a series of observations made with each test-breakfast in the several individuals of the series.

On analysing these results it is found that an infusion of tea induces a greater secretion of gastric juice than does water; a comparison of the averages of

HCl = Free hydrochloric acid. T.A. = Total acidity, expressed in terms of number of cubic centimetres of decinormal soda required to neutralise respective acidities in 100 c.c. of filtrate. P. = Peptic activity.

the total observations in 14 cases demonstrates this very clearly:—

	Water.	Tea.
HCl	42·7	53·2
T.A.	62·2	70·8
P.	6·7	8·0

In the individual cases a similar, but varying, relation is seen to obtain in all but two (Nos. 2 and 11), where the secretion is actually diminished. In three individuals a number of observations were made with a solution of caffeine (3 gr. in 10 oz. of water) with a view of elucidating the secreterogenic factor in infusions of tea. In two the averages of repeated observations showed that such a solution of caffeine was more potent than tea; whilst in the third, whilst the stimulating effect was somewhat less than that of tea, it was much greater than water.

	Water.	Tea.	Caffeine.
HCl	46·5	54·8	54·9
T.A.	68·0	77·0	79·0

the average of the total observations showing that a watery solution of caffeine and an infusion of tea are equally stimulating. The results obtained with coffee indicate that individual susceptibility is more pronounced than in the case of tea, and that whilst the averages of the total observations in the six cases where comparison may be instituted appear to show that it is a somewhat more powerful stimulus of gastric secretion than tea, this depends chiefly on its marked effect on those who may be regarded as susceptible.

	Water.	Tea.	Coffee.
HCl	41·0	51·3	56·6
T.A.	59·8	67·5	72·3
P.	7·0	8·1	8·8

Cocoa, whilst showing some degree of individual variability in its action, is a stimulus to gastric secretion more powerful than water but less powerful than tea, as is shown by comparison of the following total averages in six cases:—

	Water.	Tea.	Cocoa.
HCl	46·3	57·4	51·8
T.A.	66·9	75·1	71·5
P.	8·0	9·1	8·4

The results of the observations with milk are particularly interesting in view of its general and somewhat empirical use as a food in disorders of the stomach and in conditions of general debility. In five out of six cases in which observations were made it proved to have a stimulating effect on gastric secretion less than that of water:—

	Water.	Milk.
HCl	43·8	33·1
T.A.	63·2	83·7
P.	6·3	5·2

This peculiar relation of milk to gastric secretion depends in all probability upon the inhibitory action of the fat contained in it. It is of interest to note that whilst the stomach contents after a milk test-meal show considerably less free HCl and pepsin than after the administration of water, there is a great access in the total acidity; so far as we have been able to investigate this phenomenon it would appear to be due to the presence of fatty acids resulting from the splitting of the milk fats. A watery infusion of a meat extract is a powerful stimulus of gastric secretion, as appears from a comparison of the following averages of the total observations in 12 cases:—

	Water.	Tea.	Meat extract.
HCl	47·0	54·3	59·3
T.A.	68·0	71·6	85·6
P.	7·3	8·0	9·0

Similarly albumin water appears to exert a considerable stimulating effect on gastric secretion, as is shown by repeated observations on two individuals. The observations on the action of alcohol and tobacco-smoking on gastric secretion made on two normal individuals are of interest in that they show that either agent may have a stimulating or a depressing effect on secretion, probably in accordance with the susceptibility of the individual.

Dr. F. PARKES WEBER read a paper on the Association of Hysteria with Malingering: the Phylogenetic Aspect of Hysteria as Pathological Exaggeration (or Disorder) of Tertiary (Nervous) Sex Characters, which will be found on p. 1542 of this issue of THE LANCET.

PATHOLOGICAL SECTION.

Arteriomyomatosis.

A MEETING of this section was held on Nov. 21st, Dr. R. T. HEWLETT, the President, being in the chair.

Mr. S. G. SHATTOCK recorded under the name of Arteriomyomatosis a hitherto undescribed arterial lesion which he had observed in the vessels of a large soft fibroma removed from the connective tissues by the side of the vagina. The vessels were of the size of the smallest arterioles and presented a remarkable overgrowth of the muscular tissue. This was not disposed anatomically as in a simple hypertrophy (as in the hypermyotrophy unassociated with renal disease described by Savill or in chronic Bright's disease), but the bundles of muscle cells, in the most marked enlargements, intersected without relation to the axis of the vessel, and after the manner of a proper myoma. The muscular overgrowth was in some cases markedly asymmetrical, and might even take the form (microscopically) of a lobulated eminence. The adventitia was quite unaffected. There was no renal disease. The condition was wholly different from the peri-arteritis nodosa of Kussmaul and Maier, where the thickenings, which occurred as discrete nodular swellings on the smaller arteries, were due to inflammatory changes in the adventitia, accompanied with endothelial proliferation, the muscular tunic being displaced and thinned. In the lesion described by the speaker the thickening was diffuse, the vessel being enlarged somewhat as the nerves in the diffuse form of neuro-fibromatosis.

Papers were read by Dr. W. LANGDON BROWN on the Bundle of His from a case of Heart-block (with specimens and lantern slides); Dr. A. E. BOYCOTT on Sahli's Hæmoglobinometer; Dr. H. R. DEAN on Further Experiments on Complement-fixation and Precipitation; and Dr. J. HENDERSON SMITH on Some Experiments on Lysis.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases and Specimens.—Purpura in Acute Infective Diarrhœa in Infants.—Congenital Flexion of the Joints of the Fingers.

A MEETING of this section was held on Nov. 24th, Dr. G. A. SUTHERLAND, the President, being in the chair.

The following cases were shown:—

Dr. T. VINCENT DICKINSON: Infantilism.

Dr. REGINALD H. MILLER: (1) Chronic Interstitial Nephritis with Infantilism; and (2) Intracranial Tumour.

Dr. F. J. POYNTON: Psoriasis and Flexion of the Terminal Phalanx of the Thumb.

Dr. A. C. D. FIRTH: Congenital Absence of Patellæ with Deformity of the Nails in a mother and three children.

Dr. J. L. BUNCH: Hereditary Syphilitic Infant treated with Intravenous Injection of "606."

Dr. E. BELLINGHAM SMITH: Congenital Word Deafness and Other Defects.

Mr. HALDIN. DAVIS: Granuloma Annulare.

A specimen of Cerebral Aplasia with Hydrocephalus was shown by Dr. R. S. TREVOR and Dr. H. D. ROLLESTON.

Dr. ROLLESTON and Dr. B. J. DE W. MOLONY communicated a paper on Purpura in Acute Infective Diarrhœa in Infants. From an analysis of 100 cases of acute diarrhœa sufficiently severe to be admitted into the Victoria Hospital for Children it was found that purpura occurred in 11, all of which were fatal; the prognosis of these cases was therefore extremely grave. In 8 of the 11 cases the purpura was on the abdomen; possibly the extremely low blood pressure and the horizontal position of the patients explained why the purpura occurred on the trunk rather than on the limbs. The purpura occurred on an average on the thirty-fourth day of the diarrhœal disease and seven days before death; purpura was therefore a late and cachectic manifestation in diarrhœa of infants. The purpura was not caused by transfusion or by the use of serums.

Mr. D. C. L. FITZWILLIAMS read a paper on Congenital Flexion of the Proximal Inter-phalangeal Joints of the Fingers, after having shown four cases illustrating the condition. As a short and convenient name for the deformity

he suggested the term "hook-finger." He stated that the chief characteristics were that the first inter-phalangeal joints were flexed to a right angle, while the metacarpo-phalangeal and the terminal inter-phalangeal joints were hyper-extended and never flexed as was sometimes stated in the books. The little finger was the one most often affected, but if the condition was present in the others as well it was less marked in those that were farthest away from the little finger. The thumb was never involved. The deformity was a true congenital one and never acquired. It was probably due to maldevelopment of the anterior ligament of the joint; the hyperextension of the metacarpal joint showed that the fasciæ had nothing to do with it, though shortness of these structures was the cause usually assigned in the books. In nearly all cases the condition was bilateral, and was frequently associated with laxity of ligaments of the other joints of the body. In one case exhibited both knees could be dislocated with great ease. Other congenital abnormalities were not uncommon. If the condition was allowed to persist and more than one finger was affected, the use of the hand might be seriously interfered with. The treatment in the early cases was manipulation and massage, but in old-standing cases the ligament should be released from the front of the base of the middle phalanx by a fine-bladed tenotome passed into the joint from the side; in this way the tendons were not injured.

MEDICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Nov. 27th, Dr. J. MITCHELL BRUCE being in the chair.

Dr. F. DE HAVILLAND HALL showed a case of Polycythæmia. The patient was a man aged 53. He had had rheumatism at the age of 15. He had been rejected on examination for entry into the Marines at the age of 18 for heart disease. In February, 1908, the present illness began with pain in the right shoulder, and he was admitted into Middlesex Hospital. In June, 1910, he was admitted into Westminster Hospital suffering from pain in the right side and shortness of breath—pleurisy. On admission into hospital on Sept. 16th, 1911, the patient was cyanosed, hands blue, fingers not clubbed, conjunctivæ injected; teeth were carious. The spleen was enlarged but not tender, and the liver was not enlarged. There were enlarged superficial veins over the abdomen, and distended and tortuous veins on the inner side of the right leg, slightly enlarged on the left leg. Nothing abnormal was found in the lungs and heart. The blood pressure varied between 90 and 115 mm. of mercury. Von Pirquet's test was positive. Examination of the blood on Sept. 18th showed: hæmoglobin 119 per cent., red blood corpuscles 10,980,000, colour index 54, white blood corpuscles 18,600, polymorphs 93 per cent. On Oct. 11th venesection to 4 ounces was done. The patient expressed himself as being much relieved by it. A second examination of the blood was made on Oct. 20th, and the polycythæmia was more pronounced than on the first occasion. The patient was seven weeks in hospital and gained 4 pounds in weight.

Dr. A. F. VOELCKER showed a case of Anæmia Pseudoleukæmia Infantum (von Jaksch) in which recovery had taken place.

Mr. DUNCAN C. L. FITZWILLIAMS showed a case of Persistent Forward Dislocation of the Head of the Radius in a patient who two years ago had an injury to his left elbow. The movements of extension and flexion were excellent. On extension the head of the radius could be felt dislocated forwards. The carrying angle was increased and lateral movements could be obtained. On flexing the arm something was felt to slip, and on full flexion the head of the radius was felt to the outer side of the shaft of the humerus well above the external condyle. There was no pain with the condition.

Mr. FITZWILLIAMS also showed a case of Compound Ganglion of the Palm of the Hand in a female patient. The condition had lasted for about 15 years. The ganglion extended from about 1½ inches above the anterior annular ligament of the wrist down to the middle of the palm. It extended along all the flexor tendons with the exception of that of the thumb and the little finger. A sensation as of melon-seed bodies was felt on driving the fluid to and fro under the anterior annular ligament. The collection had been tapped many times.

Dr. F. J. POYNTON reported a case of Loss of Power in the Hand of four years' duration in a female aged 43. There had been loss of power and loss of sensation in both hands for the last four years, worse on the left side. The symptoms were thought to have begun as a result of hard work four years ago. They had increased steadily. The patient could not hold anything in either hand. Pains (as if in the bones) commenced in the thumb and hollow of the left hand and passed up the radial side of the arm to settle in the supraclavicular fossa. There was similar (but less) pain on the right side. There were occipital headaches, and cramp-like pains in the sole of the right foot and in the right side of the stomach. General weakness and wasting were present. The patient had enlarged cervical glands on the right side when 18 years old. She was nervous and emotional, and responded readily to suggestion. The pupils were normal. There was no marked wasting of either arm or forearm. In the left hand the thenar eminence was wasted, as also the hypothenar eminence. There was slight wasting similarly on the right side. The interossei were poorly developed on both sides. The trunk muscles were normal. There was no wasting of either lower limb, and the patient used them freely. There was no tremor or ataxy. Sensation was normal over the trunk and lower limbs. There was considerable blunting of the tactile sense in the upper limbs (stroking touch) uniformly distributed over both forearms and hands below the elbows. Sensation to pain was normal or rather hypersensitive; heat and cold sense normal. Reflexes in the upper arms were present and equal on both sides. Abdominal reflexes were present. The plantar response was indefinite flexor. Sensory change was very variable. On Nov. 24th the stroking touch was felt readily all over both forearms and hands, and there was hyperæsthesia to pin-pricks. No alteration in intensity of tactile sense anywhere could be made out. The left hand sweated profusely, the right to a lesser degree. The patient complained of tenderness "in bones" when the forearms were squeezed. Both thumbs could be opposed and abducted quite well.

Mr. W. H. BATTLE and Mr. H. BAZETT showed a case of Tracheal Obstruction. The patient was a female aged 42. In 1907 the patient had pneumonia and pleurisy, and since that time she had suffered with shortness of breath and stridor, and she had noticed some swelling in her neck which varied from time to time. During the same time she had had a troublesome cough, especially in the morning. On admission, on June 19th, 1911, the patient was found to have an enlarged thyroid, the enlargement being especially on the left side, while there was no obvious enlargement of the isthmus. The enlargement of the gland appeared to be uniform and the lower margin of the gland could not be defined, but appeared to extend behind the sternum. No abnormal sounds were heard in the chest, but there was some dulness on percussion over the manubrium and some dilated veins were seen over the upper part of the chest. The larynx was examined and found to be normal. On June 30th Mr. Battle made a median incision in the neck and divided the isthmus of the thyroid, and separated the gland and its capsule from the trachea, which was compressed and scabbard-shaped. The left lobe of the thyroid was enlarged and was pushing the trachea over the right side of the neck, but the thyroid did not appear to extend down into the thorax. Since the operation the stridor, mainly inspiratory, had continued, and on examination with X rays, the trachea was seen projecting from both sides of the manubrium, but more on the left than on the right. At the present time the right lobe of the thyroid was the larger in the neck, there was dulness on percussion over the manubrium, and on examination of the chest the respiratory breath sound was somewhat prolonged at the apices, and occasional crepitations were heard.

Mr. BATTLE and Mr. BAZETT also recorded a case of Tumour of the Femur in a male aged 16. About one month ago the patient knocked his left knee while at work, and on the next day noticed a hard lump above the knee. He again knocked his knee a week later. The lump gradually increased in size until shortly after the second injury, since when it had appeared to become a little smaller. After the first injury there was very little ecchymosis, but after the second injury the skin round the tumour became a dark-blue

colour. On admission on Nov. 15th a smooth, hard, rounded mass could be felt on the inner side of the lower end of the left femur. The tumour appeared to be attached to the femur and not to any of the more superficial structures; it was not definitely pedunculated, but appeared to be somewhat constricted at its attachment to the bone. On X ray examination the tumour was seen to be composed of very delicate bone of somewhat peculiar appearance.

Mr. BATTLE and Mr. BAZETT also brought forward a case of Popliteal Aneurysm in a male, aged 61 years. About five months ago the patient first noticed a small swelling at the back of the left knee. He took no notice of it and drew no one's attention to it. On August 16th, 1911, while walking, the patient developed acute pain in his right foot, which became blue and cold, this condition spreading up the leg nearly to the level of the knee-joint. On admission on August 19th the limb was cold and blue, and skin sensations were lost. The heart was enlarged but otherwise appeared normal; the urine had a specific gravity of 1024 and contained a trace of albumin. The arteries were thickened. A diagnosis of senile gangrene of the right leg was made, and on August 22nd, when a line of demarcation was becoming evident, the limb was amputated in the lower third of the thigh by a mixed flap and circular method, and the patient was discharged on Sept. 20th. Since he had been getting about with only one leg he had had pain behind the right knee and his leg had become swollen. The swelling at the back of the knee had not increased in size. On readmission on Nov. 14th the patient was found to have a swelling at the back of the left knee of the size of a small egg. The swelling exhibited expansile pulsation, which could be controlled by compression of the femoral artery. There was considerable œdema of the left leg and foot below the level of the knee, but there was no obvious enlargement of veins. With rest in bed for a fortnight, the œdema had disappeared for the most part. Nothing further abnormal was discovered in the chest or in the examination of the urine.

Dr. CHARLES W. CHAPMAN showed a case of Double Aneurysm of the Thoracic Aorta. The patient, aged 53, came under observation as an out-patient. He complained of sharp pain on the left side of his chest, passing down the left arm to the fingers, provoked by quick movements, and shortness of breath on exertion. The symptoms had lasted for eight years, but had become worse the last three years. There was no palpitation. The family history was good and the patient did not remember having had any illness. He had drunk very moderately of beer, no spirits, and was a non-smoker. He denied having had syphilis. On examination the cardiac dulness was much increased in both directions, there was impaired reasonance over the whole sternum, and a special area of dulness on the right side of the sternum over the second and third costal cartilages and extending to the right parasternal line. Over the latter area was a systolic thrill, and on auscultation loud harsh to-and-fro murmurs were heard; there was also a systolic murmur at the apex. The radial arteries were unequal. Wassermann reaction was positive. Examination by the X rays showed a pulsating swelling on the right side of the ascending aorta where the dulness had been observed, while in addition a smaller but freely pulsating aneurysm was seen higher up on the left side of the sternum.

Dr. CHAPMAN also showed a case of Aneurysm of the First Part of the Aorta in a man, aged 32. He complained of pain in the right breast and shoulder which had existed for seven months. Valvular disease had previously been detected. The patient had been to India, but denied having contracted specific disease or having had any illness. The man was pale and generally out of health; he had a more or less circular area of dulness with pulsation extending from the right side of the sternum for nearly 3 inches to the right, a harsh systolic murmur over the same area, and well-marked diastolic shock. There was much tenderness on pressure or friction. The apex-beat was just above the sixth rib and nearly an inch to the left of the nipple line. The impulse was feeble; arteries little thickened. Beyond a few scattered crepitant râles at both pulmonic bases there was nothing to note in the other organs and the urine was normal. Wassermann reactions were taken and were positive on both occasions. The pain was much relieved under rest and the free exhibition of iodides, but the improvement was most marked when Plummer's pill was added to the prescription, both as regards pain and force of pulsation. The patient remained in hospital for some months.

Mr. EDRED M. CORNER showed cases illustrating results of Cellulitis of the Hand. Case 1 was a male, aged 34, whose right hand was affected. He had been in hospital eight months ago, when an operation was performed. The patient was doing his work (manual) well; the only disability from which he suffered was that his hand ached after hard work. Case 2 was a male, aged 46, and had the trouble in the left hand. He was in hospital two and a half years ago, when he had six operations. He did his work (manual), but the hand became stiff if it was cold, and it ached in cold weather and after work. Case 3 (right hand) was a male, aged 59, who was in hospital 16 months ago, when he had an operation. He did light work, but could not close his hand to grasp, and the hand easily ached. Case 4 (also right hand) was a male, aged 59, who was in hospital 18 months ago, when he had three operations. He had lost one finger. But beyond sensitiveness to cold the hand was as good as it was before it became affected with cellulitis. Case 5 was a male, aged 50, who was in hospital 16 months ago with the trouble in his right hand. He had two operations. The hand was contracted and much disabled, and he could not grasp. He had a nodule of inflamed palmar fascia such as was found in Dupuytren's contraction. The hand felt the cold very much. The sixth case was that of a male, aged 38, who also had the right hand affected. He was in hospital two and a half years ago, when he had three operations. He could not close his hand to grasp. The hand was cold and blue, and was very sensitive to cold and changes of weather. In the seventh case, that of a male, aged 30, the left hand was affected. He was in hospital six months ago, when he had an operation. He did his work (heavy), his hand giving him no trouble except that it ached in rainy weather. Case 8 was a male aged 39; right hand. He was in hospital nine months ago, when he had five operations. He did his work (manual), but his wrist was stiff and the wound still remained unhealed. Case 9 was a male aged 17, with right hand affected. He was in hospital nine months ago, when he had two operations. He did his work (manual), his hand only troubling him when riding (he had a stiff finger). The tenth case was a female, aged 45, who had the affection in the right hand. She was in hospital six months ago, when she had two operations. She was married and used to do housework. Now she could not do her work as she could not close her hand to grasp; moreover, she felt changes of weather and temperature acutely in the hand. The nails were cracking. Case 11 was that of a female, aged 65, whose right hand was affected. She was in hospital two years ago, when she had one operation. She had difficulty in doing her simple laundry work. She did not feel the cold, but the hand ached whilst at work and afterwards, preventing her sleeping at night. The pain was felt across the knuckles.

Dr. J. WALTER CARR brought forward a case of Infective Endocarditis; recovery. The patient was a woman, aged 26. She had rheumatic fever when 21, and had suffered from slight breathlessness and occasional giddiness since. She was confined in January, 1911, and had a good deal of headache and giddiness after. On Feb. 28th she suddenly developed right hemiplegia, without loss of consciousness, doubtless from embolism. She was admitted to the Royal Free Hospital on March 10th. The heart was slightly dilated and there was a systolic murmur at the apex. Staphylococcus pyogenes was found in the blood. For the next five weeks she became steadily worse, and the temperature was very irregular, varying between 98° and 104°. The heart became greatly dilated, dulness extending from one inch to the right of the sternum to over an inch outside the left nipple line. Pulmonary bases were much congested. The urine frequently contained blood and albumin, probably from renal embolism, and the right kidney was palpable and tender. Three injections were given of an autogenous vaccine, containing respectively 300, 400, and 500 millions of staphylococci. No apparent benefit followed, the patient continuing to lose ground. Anti-staphylococcic serum was next injected, six times in all, 10 c.c. twice and afterwards 15 c.c. After the last injection the temperature became normal and gradual

improvement followed. The patient left the hospital on June 30th. She was in good health and doing full, ordinary household work without any discomfort. Mitral regurgitation was still present and the heart was slightly enlarged. The hemiplegia had passed off, except for slight weakness of the right hand. The lungs were clear and the urine normal.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Cases and Specimens.—Influence of the Adrenal, Pineal, and Pituitary Glands upon Primary and Secondary Sex Characters.—Intestinal Concretions.

A PATHOLOGICAL meeting was held on Nov. 16th, Mr. G. P. NEWBOLT, Vice-President, being in the chair.

Dr. K. A. GROSSMANN showed Twin Embryos—four months.

Mr. R. W. MURRAY showed Intussusception in an adult.

Mr. F. T. PAUL: An Appendix from a girl, aged 11, completely filled with a concretion which extended half an inch into the cæcum; she never had definite appendicitis.

Mr. W. THELWALL THOMAS showed: (1) A Myeloid Tumour from the palm of the hand, unconnected with bone; (2) a simple Duct Papilloma of the Breast (there was a discharge from the nipple); (3) an Adenoma of the Palate; and (4) Four Calculi removed from the Bulbous and six from the Prostatic Urethra.

Mr. T. C. LITLER JONES showed Melanotic Sarcoma of the Liver, with secondary infection of bacillus aerogenes capsulatus; the eye was removed two years before for glaucoma.

Dr. R. J. M. BUCHANAN showed Traumatic Pontine Hæmorrhage from a prize-fighter.

Dr. ERNEST E. GLYNN showed Infective Endocarditis, with subarachnoid cerebral hæmorrhage.

Dr. J. H. WILLETT showed Carneous Mole, Channeled Polyp, and Ovarian Fibroma with twisted pedicle.

Dr. E. GLYNN read a note on the Influence of the Adrenal, Pineal, and Pituitary Glands upon Primary and Secondary Sex Characters. He referred especially to the occurrence of malignant adrenal hypernephromata in female children with precocious development and hirsuties, to bilateral adrenal hyperplasia in female pseudo-hermaphrodites, and to the occurrence of true sexual precocity in tumours of the pineal gland.—Dr. T. R. GLYNN referred to the developmental relationship between the adrenal cortex and sex glands.

Dr. O. T. WILLIAMS read a paper on Intestinal Concretions. He demonstrated three series of concretions from the gall-bladder, intestine, and appendix, and compared and contrasted their chemical constitution. He suggested that their occurrence was evidence of general disorder of calcium and fat metabolism, and that the concretions were excreted by the intestine and the appendages.—Dr. J. LLOYD ROBERTS referred to a case of ulcerative colitis, ultimately fatal from perforation, in which the only symptoms for long periods were the passage of large quantities of mucous casts.—Dr. M. H. F. IVENS, Dr. GLYNN, and Dr. W. BLAIR BELL also spoke.

Wound of the Thoracic Duct.—Sacrococcygeal Meningocele with Imperforate Anus.—Nerve Anastomosis in Infantile Paralysis.

A MEETING of this society was held on Nov. 23rd, Dr. T. R. BRADSHAW, the President, being in the chair.

Mr. PAUL read a note of a case of Wound of the Thoracic Duct due to deep dissection of the neck for malignant glands. Compression having failed, the duct was successfully ligatured on the fifth day. Having reviewed other methods of treatment, he concluded that ligature was the best and should be employed as soon as injury to the duct was recognised.—Dr. H. F. PHILLIPS HUNT, under whose care the patient was, said that during the period that chyle was flowing the condition was one of extreme lassitude and drowsiness. The patient described her feelings as if she were in a far-off dream, that voices sounded dim and far away, and that she had to exert considerable mental effort before being able to answer questions. The temperature ranged from 100° to 102° F., and fell to normal 48 hours after the flow of chyle had ceased. She required an unusual amount of anæsthetic.—Mr. THELWALL THOMAS mentioned a case of wound of the duct following removal of tuberculous glands. The same evening free oozing took place of a clear discharge, saturating the dressings. The next day there formed a large opalescent clot distending the neck. On examination no definite spot could be found from which the oozing came. The wound was firmly packed with gauze. The patient was given a diet of tea and beef-tea. Recovery was uneventful.—Mr. RUSHTON PARKER mentioned the case of a girl, aged 10, from whom he excised tuberculous glands in the left supra-clavicular region. At the subsequent dressing abundant clear watery fluid escaped. No symptoms whatever resulted. If it were suggested that this fluid came from the lymphatics he stated that in excising glands from the thigh he had knowingly cut the largest lymphatics, but had never seen the escape of clear fluid afterwards.

Dr. ERNEST W. LEWIS read a note on a case of Sacro-coccygeal Meningocele in an adult associated with Imperforate Anus. Dr. Lewis gave a detailed account of this case and discussed the causation, varieties, prognosis, and treatment of imperforate anus.—Mr. R. C. DUN'S experience was that Dr. Lewis's patient showed the common variety of imperforate anus met with in females. He had notes of 45 cases on which he had operated—31 males, 14 females. The deformity in 13 of the female cases was similar to that in the case under discussion. The mortality in this series of cases was 22 per cent.

Mr. MURRAY read a note on five cases of Infantile Paralysis in which he had performed Nerve Anastomosis. In every case it was judged that sufficient time had elapsed to permit of natural recovery. Electrical reactions were always taken under anæsthesia. The operations were performed four or five years ago and the results were most disappointing, for in no instance was there any improvement as the direct result of the anastomosis.—Dr. W. B. WARRINGTON mentioned that a detailed account of these cases had been published in THE LANCET of April 2nd, 1910. He alluded to Stoffel's criticism of that paper and said that this writer claimed that the individual fibres to the muscles kept a definite topographical position throughout the nerve trunk and that this position could be recognised from experience, and hence a more scientific operation undertaken.—Mr. DUN mentioned four cases of infantile paralysis in which he had performed nerve anastomosis without improvement.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Exhibition of Cases and Specimens.—Acute Inversion of Uterus.—Early Rising after Cœliotomy.

A MEETING of this society was held at Sheffield on Nov. 17th, Dr. J. B. HELLIER, the President, being in the chair.

Dr. J. E. GEMMELL (Liverpool) showed specimens of: (1) Carcinoma Corporis Uteri; (2) Carcinoma Corporis Uteri with Fibroid; and (3) Diffuse Adeno-fibroma Uteri. He described their macroscopic and microscopic appearances, and urged the desirability of performing hysterectomy for all cases of fibroid seen at the menopause.

Mr. A. W. CUFF (Sheffield) related cases of: (1) Ureteral Calculus removed per vaginam; and (2) Vermiform Appendix in a Femoral Hernia.

Dr. A. DONALD (Manchester) read notes of a case of Wertheim's operation for Cancer, which was followed by sloughing of the abdominal wall, possibly due to the pressure of the retractor used at the operation.

Mr. MILES H. PHILLIPS (Sheffield) reported three cases of Acute Inversion of the Uterus which he had seen in consultation shortly after their occurrence. In each case, as the patient was profoundly collapsed, no attempt was made at immediate reposition. There had been little or no post-partum hæmorrhage. The shock was treated by saline infusion to which pituitary extract and morphia were added. After intervals of two, five, and 20 hours respectively the patient had sufficiently rallied to warrant operation. Under anæsthesia the uterus was in each case replaced without any great difficulty. All three patients recovered. It was then argued that the presence of severe shock should contra-indicate the usual text-book instructions to attempt immediate reposition. The secondary shock

so caused is likely to turn the balance against the patient. Analysis of 184 cases, collected chiefly from English records, supports the contention. The total mortality was 43 (23·4 per cent.). Of 79 cases in which the uterus was immediately replaced, *in the presence of marked shock*, 24 (over 30 per cent.) died. In 23 cases, in which it is definitely stated that there was *no shock*, immediate replacement was followed by recovery in each instance. In 10 cases there is no note as to the presence or absence of shock (probably, therefore, it was not present in any marked degree); immediate replacement was successful in each of these cases. In 17 cases death occurred with the uterus unreduced, generally from shock, before the arrival of the medical practitioner, who recorded the case. In 45 cases the uterus was allowed to pass into the state of chronic inversion, which was treated later, with success in every instance. In 2 cases death was due to septic infection. Of the 43 deaths, 41 took place within a few hours. The figures also show that immediate replacement of the uterus is followed by fatal results in 21 per cent. of cases, whereas in the 47 cases allowed to become chronic only 2 died. The intermediate line of treatment, indicated above, was strongly advocated.

Dr. A. J. WALLACE (Liverpool) read a short note on the results of early rising from bed of patients who had undergone abdominal and vaginal cœliotomies. After mention of the reasons for the adoption of the practice the guiding rules were stated as follows: recovery from operation must be good; pulse-rate and temperature must be normal; all nausea and vomiting must have ceased; the abdominal wound must be healed or be healing by first intention—the incision having been so made that the resulting cicatrix was supported by muscular tissue (the Lennander or Pfannenstiel incision); patients were merely encouraged to leave their beds, compulsion being never employed. Of 400 patients who underwent major operations in hospital 283 left their beds as soon as they felt disposed to do so, the majority on the seventh and eighth days. The discharge from hospital was generally on the fifteenth or sixteenth day after operation. The cases included every variety of operation for gynæcological ailments. In the great majority of cases the general condition of the patients was distinctly better than had been the case with patients confined to bed for two or three weeks. A few unfavourable results had to be recorded—slight pyrexia without definite cause (two cases); redness and swelling around the wound (two cases); secondary hæmorrhage from perineal wound (one case); a patient aged 64 who got up on the sixth day developed bronchitis; post-operative thrombosis (three cases) in mild degree.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Fatal Case following Injection of "606."—Spinal Anæsthesia in Prostatectomy.

A MEETING of this section was held on Nov. 3rd, Mr. R. H. WOODS, the President, being in the chair.

Mr. H. MOORE reported a case of early General Paralysis of the Insane treated by "606," with a fatal result. The patient, aged 25, was given 0·5 gramme intravenously. A severe reaction followed, his temperature rising to 103° F. It was normal next morning, and he left the hospital on the fifth day. Wassermann's reaction, which had been negative before injection, was positive four days after. Six weeks later, his general condition being much improved, but Wassermann's reaction being still positive, he was again given 0·5 gramme. The reaction was very severe, his temperature rising to 105°, with much diarrhœa, vomiting, and general pain. The reflexes, which were all exaggerated before injection, disappeared. He was much better the following morning, but that afternoon he had a second rigor, with rise of temperature to 102°. His general condition became rapidly worse—he got ptosis of the left eyelid, bilateral paresis of the limbs, and difficulty of articulation, and died that night.—The PRESIDENT said that the administration of salvarsan had become firmly established. Notwithstanding Mr. Moore's case, he thought it a safe proceeding with proper technical precautions. In the case of vaccination the General Medical Council exacted an extraordinary length of time for its study, in the case of intravenous and other injections they did not exact any education at all. He often gave it in an ambulatory way, but until more was known about it, it was doubtful whether it ought to be given outside hospital.—Mr. ANDREW CHARLES suggested a cumulative effect.—Dr. T. G. MOORHEAD said he could hardly agree that the administration of salvarsan in an ambulatory manner was safe, the last injection given by him having been followed by severe symptoms almost identical with those in Mr. Moore's case. The patient was extremely cyanosed, the tongue swollen, and he was complaining of tingling in the legs; but he was perfectly well next morning.—Sir JOHN LENTAIGNE thought the administration of this drug should not be undertaken unless the patient was under control in hospital for at least three days. In the first four cases in which he had administered it the symptoms were most alarming. If the patients were thoroughly cleared out before injection it would be better. He had tried this and found a very great difference in the violence of the reaction, and the patients were free from constitutional disturbances afterwards. He would on no account treat a patient and allow him to walk home afterwards.—Mr. G. E. P. MELDON asked the exact cause of the patient's death. If death had been directly due to the salvarsan it was probable the patient would have died within the first few hours, but apparently he got over the early reaction and succumbed to a second or later reaction.—Mr. W. I. DE C. WHEELER said he thought Mr. Moore's case by no means the only Dublin patient who died after salvarsan. In the treatment of paralytic cases it was found to be so harmful that in lunatic asylums it had been abandoned. He had given up the intramuscular injection in favour of the intravenous method.—Mr. K. E. L. G. GUNN said one of his cases had caused him much anxiety. A youngish man with very bad syphilis, with whom the ordinary treatment had failed, after injection was fairly bad for some hours, but in about 20 hours afterwards he was found to be in a very serious state, and although he recovered he was very near death.—Mr. A. J. M. BLANEY asked, Was Mr. Moore justified in giving salvarsan in the case brought before them?—Mr. PEARSON said in his experience of ten cases it was rather the rule to get no reaction. In some cases the injection was followed by diarrhœa, but in no case was there a great rise in temperature.—The PRESIDENT spoke of his experience of over 40 cases where this drug was administered, and in all except the first he had given it intravenously by gravitation, using a boiled cotton-wool filter. In none of the cases was there anything like a severe reaction.—Mr. MOORE, replying, said that in two or three cases where the patient had a very slight reaction at first, in about 36 hours afterwards there was a severe reaction. Alcoholic patients should be carefully dealt with. He always prepared the patient as for a major operation. The drug should always be made fresh, and the saline solution should be made at the same time with boiling water and then allowed to cool. With regard to the question as to the cause of death in the case brought before the Academy he could not say what really was the cause.

Mr. R. A. STONEY in a paper on Spinal Anæsthesia in Prostatectomy said that one of the most important questions in connexion with prostatectomy was that of a suitable anæsthetic. Owing to the age, condition of the heart, lungs, vessels, and kidneys, these patients were often unsuitable subjects for an anæsthetic, even though much might be done to mitigate its evils by careful previous preparation of the patient and the reduction of the duration of the anæsthesia by rapidity of operating. Another point of great importance, to which sufficient attention was not usually paid, was hæmorrhage. These difficulties were best met by the use of spinal anæsthesia as exemplified by a case in which a 5 per cent. solution of novocaine, with a small percentage of adrenalin, was used. The patient, a man aged 75, had extensive chronic bronchitis and a weak, irregular pulse, pointing to fatty degeneration of the heart, and atheroma of the vessels. The prostate was removed without trouble to the operator or pain to the patient under spinal anæsthesia. There were no unpleasant after-effects. The hæmorrhage, both at the operation and afterwards, was remarkably slight, all tingeing of the urine with blood having ceased after 36 hours. The patient was propped up in bed immediately after the operation, and was sitting in a chair on the third day. He left hospital with the suprapubic wound closed, and passing his urine in a normal manner, one month after operation.—Sir CHARLES BALL said that some

years ago, when novocaine first came into use, he saw a considerable number of cases of spinal anæsthesia in Paris. In most of the cases the anæsthesia was not complete, and in many chloroform had to be administered before the operation was finished. He had also heard of several serious complications arising after operation with spinal anæsthesia, notably paraplegia. He considered ether safer than spinal anæsthesia.—Mr. GUNN had tried spinal anæsthesia in five cases of prostatectomy, and while in theory it might be admirable it had not worked successfully with him. Mr. Stoney had emphasised that spinal anæsthesia lessened the hæmorrhage following the operation. He was of opinion that the bladder regained its tone more quickly after light ether anæsthesia, and that this was a most important factor in the control of post-operative hæmorrhage. He was inclined to think that the general anæsthetic got too much blame. He was informed by those who used spinal anæsthesia in a large number of cases that chest complications were more numerous after it than after general anæsthesia.—Mr. PEARSON understood Mr. Stoney to say that spinal anæsthesia had no effect on the heart and lungs, but in his (Mr. Pearson's) opinion it had a very marked effect on the blood pressure. Nor did he agree with Mr. Stoney that adrenalin minimised the tendency to hæmorrhage.—Mr. STONEY, in reply, said that stovaine did not appear to be so satisfactory as novocaine. The latter was apparently the least toxic of all the drugs, especially when combined with adrenalin, and he thought that in this combination it had not the effect of reducing the blood pressure. He believed that the technique was probably the cause of a great many of the failures. Seeing that the recovery was fairly rapid, the effect of adrenalin in contracting the small vessels more than counteracted the loss of tone in the bladder during the first hour after operation.

SECTION OF MEDICINE.

A Triad of Clinical Records.—Gangrenous Dermatitis.

A MEETING of this section was held on Nov. 10th, Sir JOHN MOORE, the President, being in the chair.

Under the heading of "A Triad of Clinical Records," the PRESIDENT submitted the clinical notes of three cases which had recently come under his observation in practice. The first was that of a married woman, aged 34 years, with chronic perihepatitis and interstitial hepatitis, and the prominent symptoms of ascites, jaundice, and hæmatemesis. She first came under notice in April, 1909, with the signs and symptoms of purpura hæmorrhagica, and complained of a feeling of fulness in the abdomen, which was distended, and of constant drowsiness. On Feb. 14th last 440 ounces of bile-stained fluid were evacuated by paracentesis abdominis. In October, 1911, she went into the Meath Hospital for the third and last time. On Oct. 10th paracentesis abdominis was again performed, and 580 oz. of serous effusion were drawn off. The liver was examined next day; it was enlarged, and its surface was apparently nodular, like a hob-nail liver. After death, on Oct. 18th, the capsules of the liver and spleen were remarkably thickened, and their free surfaces were deeply pitted and indented. The second case was an example of the beneficial effect of thoracentesis in empyema. The patient, a lad of 18, contracted left pleuro-pneumonia, which ran an atypical and unsatisfactory course. Tubercle bacilli were frequently looked for, but never found in the expectoration. Suddenly a localised empyema on the left side seemed to give way into the pleura at large, and the patient became cyanosed and deadly ill. Dexiocardia was discovered one morning. A free opening was made into the left pleura, and large quantities of fœtid pus were evacuated without resection of a rib, the critical state of the patient forbidding such a procedure. The young man made an excellent, though protracted, recovery. In the third case, a rapidly growing mediastinal lympho-sarcoma in a man, aged 71, closely simulated thoracic aneurysm because of the symptoms and signs which it produced. The new growth involved the œsophagus, stomach, and liver, and spread into the neck, compressing the trachea and pushing the larynx towards the left side of the neck. The prominent symptoms were hoarseness and then aphonia, spasmodic cough, dysphagia, vomiting, or rather regurgitation of food, and hæmoptysis. There was an almost complete absence of pain. Microscopically the appearance suggested small round-celled carcinoma, but Dr. William Boxwell, who made the necropsy, was inclined to look upon the growth as a variety of lympho-sarcoma.—Mr. R. H. WOODS said he had seen the third of these cases in consultation. The patient had a peculiar stridor, which the trained ear could detect as being due to stenosis or to compression of the trachea. The pitch of such stridor varied with the situation of the narrowing.—Dr. W. G. SMITH expressed his surprise at Sir John Moore's attaching any importance to "cancerous cachexia." The speaker entirely refused to believe that cancer produces cachexia *per se*, and instanced many uterine and breast cancers of enormous size where no cachexia existed. Cachexia in cancer is due solely to the growths preventing nutrition.—Dr. J. M. FINNY, Dr. BOXWELL, and Dr. T. P. C. KIRKPATRICK also spoke.—Dr. J. LITTLE, from the chair, summed up the discussion, and mentioned that weight may be attached to the effects of leeching in intra-thoracic tumour. Leeches always afforded at least temporary relief in cases of aneurysm.

Dr. F. C. PURSER described a series of 15 cases of Gangrenous Dermatitis, most of them suffering from enteric fever, who had presented a condition fairly to be described as epidemic gangrenous dermatitis. In every case but two, where they were low on the back, the gangrenous areas were confined to the buttocks. One of the patients, a girl aged 6, died from diphtheria, but not of the dermatitis. A sixteenth case, occurring some three to four weeks after the others, was alluded to. It was that of a boy, aged 3½, who died from broncho-pneumonia, double empyema, and purulent pericarditis. In this case alone was the gangrene preceded by inflammation. A detailed account of all the cases will be published later.—Dr. FINNY recalled a case he had shown some years ago at the Academy, which began in impetigo. It had ended fatally. He laid great stress in the search for a cause on the lowered resistance of the patients.—Mr. O'C. J. DELAHOYDE and Dr. H. C. DRURY described cases they had seen, the one of gangrenous dermatitis complicating vaccinia, the other varicella.—Dr. J. A. MATSON and the PRESIDENT also spoke.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

A meeting of this society was held on Nov. 22nd, Dr. F. H. Jacob, the President, being in the chair, when the following cases and specimens were shown:—Mr. A. R. Anderson: Two Calculi removed from a sac in the posterior wall of the bladder by suprapubic operation. The sac walls were quite thin, and apparently consisted of mucous membrane and peritoneum. It was of just sufficient size to contain the stones. There was no prostatic enlargement. The interesting points were the rarity of the condition and the failure to detect the stones after repeated examinations with a sound. Mr. Anderson also showed a child with Sarcoma of the Right Lower Jaw.—Mr. W. M. Willis: Case of removal of the right half of the Thyroid Gland for recurrent attacks of dyspnœa due to the lower end of the thyroid becoming impacted between the sternum and the trachea. Operation was performed under local anæsthesia subsequent to the injection of omnopon and scopolamine.—The President: Case of Fibro-angioma of the Breast (shown last year), showing result of treatment by radium. A lump on the scalp and another in the thigh had also diminished in size, while one on the lip had disappeared; these had had no treatment. A microscopic section of the fibro-angioma was shown. This case has shown a decided improvement under the treatment.—The President also showed a case of Carcinoma of the Pylorus and a case of Cerebellar Tumour, with headache, nystagmus, optic neuritis, and staggering gait.—Mr. A. R. Tweedie: (1) Specimen from a case of Congenital Atresia of the Œsophagus and (2) specimen from a case of Chronic Laryngitis, with microscopical section. Also case of Intranasal Malignant Disease—probably Endothelioma. Removal of upper jaw, portion of the ethmoid and exposure of the sphenoidal sinus (preliminary ligation of external carotid and laryngotomy); microscopical section was also shown.—Dr. C. H. Cattle: A case of Raynaud's Disease in a man aged 58. The attacks began seven weeks ago with numbness and pain in the tip of the left index finger. These sensations gradually spread to all the finger-tips of both hands, which gradually became blue. The thumbs were not affected. The blueness varied in tint and was worse on exposure to cold.—Mr. Kenneth Black: Skiagrams—(1) A case of Dislocation of the Back without fracture; and (2) a case of Osteomalacia of the Tibia.—Mr. E. Bigg and Mr. Black: A case of Fracture

with Dislocation of the Back. The patient was struck in the middle of the back a slanting blow by 14 cwt. of stone. Following primary shock were noticed—first week, absence of left knee-jerk, afterwards recovered; third week and later, anæsthesia of front of left thigh, wasting of left thigh muscles, especially adductor longus and vastus internus. Pain in hip and right lumbar region, especially marked after exercise. These conditions persisted. A skiagram showed fracture and dislocation of the third lumbar vertebra; this vertebra was displaced laterally to the left, it was also rotated to the left, the spinal canal being the axis of rotation. The nerves had probably been trapped as they passed through the foramina and accounted for the trophic manifestations, &c.—Mr. Black and Dr. F. Rupert Snell showed a case of Fracture of the Back without dislocation, and a case of Otitis Media in a boy aged 2.—Mr. C. H. Allen showed a case of Lateral Anastomosis and subsequent resection of bowel for carcinoma of cæcum, and a case of Nephrectomy for Pyonephrosis due to Calculus.—Dr. W. T. Rowe showed a case of Leukæmia in a male aged 62.—Dr. Ryland showed an interesting case of Congenital Syphilis, and Dr. J. Smith a Cretin aged 21 years.

CLINICAL SOCIETY OF MANCHESTER.—A meeting of this society was held at the Children's Hospital, Gartside-street, Manchester, on Nov. 21st, and the following cases were shown:—Dr. H. T. Ashby showed a case of Migraine in a child of 4, and an infant suffering from Splenic Anæmia.—Mr. E. S. Bishop and Dr. C. H. Melland showed a man of 23 on whom Partial Gastrectomy had been performed in September, 1911, for cancer of the pyloric end of the stomach, and showed the specimen. The patient had made an excellent recovery and had gained several pounds in weight since the operation.—Dr. J. G. Clegg showed several cases illustrating the value of Trephining of the Sclero-cornea for glaucomatous conditions of the eye.—Dr. N. C. Haring showed cases illustrating the Paraffin Treatment of Atrophic Rhinitis. In one case the paraffin had wandered on to the surface of the nose and had to be surgically removed.—Dr. C. C. Heywood showed a case of Congenital Ataxia in a girl of 6. The condition had markedly improved with massage and general tonics.—Dr. H. R. Hutton showed a girl with Unusually Distributed Paralysis.—Dr. R. W. Marsden showed a case of Phthisis Pulmonalis with a cyst on the true vocal cord, and a case of Congenital Syphilis with complete occlusion of the nasal pharynx and rhinitis caseosa.—Mr. H. H. Rayner showed a boy of 13 with a Dental Cyst arising in connexion with the left upper molars. He also showed skiagrams of the Hip-joints of a child who had been treated for six months by fixation for congenital dislocation of the hip-joints. One joint is in correct position and is strong and useful. The other, not being satisfactorily reduced, has again been put up in plaster.—Dr. J. Wharton showed a case from whom the left eye had been removed for Sarcoma of the Choroid, and showed the specimen. He also showed a case after Capsulectomy for Closed Pupil, a case after the Trephine Operation for Glaucoma, and one with a Dislocated Lens.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held in the Faculty Hall, Glasgow, on Oct. 25th.—The President (Dr. A. W. Russell) opened the session with a paper on Cancer of the Uterus: Some Practical Aspects of its Diagnosis and Treatment. He referred to the frequency of malignant disease and belief that it was on the increase, and pointed out that the uterus is the organ most frequently affected. Cancer of the cervix was more frequent, more insidious, and more difficult of early diagnosis than that of the body, and he urged immediate examination in all cases where there was the slightest irregularity of hæmorrhage, or any change in the quantity of the discharges, especially if accompanied with impairment of the general health. He also emphasised the necessity of diagnostic curettage. In discussing the treatment he said that patients were greatly benefited by operations which fell short of the extensive modern operation, such as simple vaginal and abdominal hysterectomy, or even curettage of the necrotic cervix followed by the use of the cautery, or applications such as acetone and formalin. In conclusion, Dr. Russell summarised his impressions of the value of various radical operations, and said that the less extensive (especially Schauta's) seemed to give greater comfort than could be secured by the more extensive operation.—Dr. W. D. Macfarlane, jun., read notes of Three Cases of Malignant Disease of the Uterus treated by Vaginal Hysterectomy. Two were epitheliomata of the cervix of several months' duration, and the third was malignant disease of the body and cervix internally. All three patients were alive and free from recurrence—4, 3½, and 2½ years after operation. During 1910 and 1911, out of 35 cases of cancer of the uterus he had seen, 22 were inoperable; 10 hysterectomies had been performed with 4 recurrences. Of the 22 inoperable cases 7 had died. Operability depended entirely on the point of view of the operator. He selected his cases, and in advanced disease used curette and cautery and regular application of pure acetone through a Ferguson's speculum. He advocated the radical operation (Wertheim's) in early cases, but in advanced cases, with marked involvement of the parametrium and glands, he contented himself with a simple abdominal hysterectomy.—In the discussion which followed Professor J. Munro Kerr said that his practice was to perform the more extensive (Wertheim's) operation. He found that about 70 per cent. of cases were operable and the results were satisfactory.—Mr. D. Duff maintained that the problem to be faced is that of extirpating, not only the tumour, but also the lymphatic area.—Dr. Louise McIlroy was of opinion that the success of incomplete operations was due to the fact that some cancers were of the slow-spreading type.—Dr. D. Shannon advocated Wertheim's operation as the one which held out most hope of cure.—Fresh specimens were shown by Dr Russell, Professor Munro Kerr, Dr. J. M. Stark, Dr. Macfarlane Dr. G. Balfour Marshall, Dr. Shannon, and Dr. Munro Campbell.

Reviews and Notices of Books.

Spirochætes: a Review of Recent Work with Some Original Observations. By W. C. BOSANQUET, M.D. Oxon. With one coloured plate and figures in the text. London and Philadelphia: W. B. Saunders Company. 1911. Pp. 152. Price 12*s.* net.

IN view of the present rapid and voluminous output of scientific work, which shows no signs of diminution, any observer who is content to devote himself to taking stock of knowledge already ascertained is doing an immense service. The work implied by this course is not showy, but it possesses the more solid value of appealing to a much larger audience. Few of us who are engaged in research in different biological fields can afford the time to examine into what our neighbours are doing in their several ways. We have quite enough to keep abreast of our own particular line of investigation. But there is generally time to read through a compendium, if sufficiently short, of labours achieved in other fields; and to those authors who thus facilitate the growth of general knowledge in the scientific world, such as Dr. Bosanquet, we are greatly indebted. Even a pure compilation is welcome; but the volume now before us is far from being definable in such terms, unless indeed every work of a comprehensive nature, and thus necessitating much reference to the work of others, is to be looked upon as a compilation. But there are two kinds of compilations. In the baser sort we have an account of a subject written by a person who is not known in connexion with that subject and whose absence of authority may be accompanied with an absence of the critical faculty due to personal equipment. The proper type of a work of this nature is like that before us, where the author has devoted time to the subject matter and has embodied in his *résumé* facts known to him at first hand.

The subject upon which Dr. Bosanquet writes is one of as great interest as is any subject to-day. The organisms known roughly as spirochætæ not only have a purely biological interest of their own, but are associated with many diseases the etiology and cure of which are a matter of moment. But in spite of what is already known about

these organisms—and the author gives a bibliography "by no means exhaustive," which nevertheless occupies 20 pages—their systematic position in the organic world is not at all definitely settled. It is, in fact, uncertain whether they are protozoa or more nearly allied to the schizomycetes (bacteria). In favour of the former view is the fact that they cannot be caused to multiply in "cultures," like most bacteria. Here, however, we cannot speak with final decision, for there are bacteria which lack this characteristic of their group. The question of structure is also one which has many exponents not in entire agreement with each other. A certain amount of doubt would seem, according to Dr. Bosanquet, to complicate some of the more important aspects of these creatures, such as, for example, the actual existence of the spiral vibratile membrane. It may be remarked, however, that in regard to this point and to other salient points of anatomical structure two recent communications in the *Quarterly Journal of Microscopical Science*, published too late to be of service to Dr. Bosanquet, confirm the animal view of the nature of spirochætæ, and appear to settle some disputed points.

While there is this difficulty about the larger forms of spirochætæ it is clear that the doubt must be much greater when we come to study the smaller forms, such as the parasites of syphilis and yaws. What is known, however, would appear to tend towards a uniformity between the larger and smaller spirochætæ. In view of the great importance which these organisms have gained of late years, particularly since their discovery by Schaudinn in syphilis, it is remarkable to note and remember that the first species of the group or genus which was discovered was a purely free-living form, named by Ehrenberg spirochæta plicatilis. This is, moreover, not the only free-living form known to science. For the hot springs of Dax yielded to Dr. Cantacuzene so lately as 1910 a species which he named S. daxensis and which is also one of the larger forms. It is, of course, possible that no specific differences really divide this form from Ehrenberg's original spirochæta. Indeed, as the author of the present volume admits, the question of species *versus* forms in this little-known group is another of those matters which are by no means settled. Inasmuch as Dr. Bosanquet enumerates over 50 organisms of this genus to which specific names have been applied, it is probable that future researches will necessitate some reduction. But it is plain that the time for a "catalogue raisonné" has not yet arrived.

In the meantime, Dr. Bosanquet sets forth those forms which have been separated, and at least presents us in an easily assimilable form with the main structural and classificatory facts known respecting this most important assemblage of organisms. He is to be congratulated on having compressed so useful a *résumé* into so few pages. The price of the book is rather high.

The Prevention of Infectious Diseases. By ALVAH H. DOTY, M.D., Health Officer of the Port of New York. London and New York: D. Appleton and Co. Pp. 281. Price 10*s.* 6*d.* net.

IN his preface the author tells us that he has aimed to deal with prevention of infectious diseases from a practical standpoint, to present the latest knowledge relative to their transmission, and "so far as possible to prove the fallacy of certain theories regarding this subject which have long been accepted and which aid in the extension rather than in the prevention of these diseases." Although the book has a comprehensive title it is chiefly concerned with the prevention of infectious diseases brought by ships, and in this country will be mainly in demand by medical officers of our port sanitary authorities. It may be said at once that many of the fallacious theories against which Dr. Doty argues—for example, that the occurrence of infectious disease among the passengers or crew calls for rigorous disinfection of cargo—have long been abandoned, if, indeed, they ever were entertained, in the sanitary practice of British ports, and that some of the preventive measures which are advocated—such as the provision of an adequate isolation hospital at every port—have so long been thought essential to our home administration that it is surprising to find it necessary to press for them, on the ground of "latest knowledge," in the United States.

While adducing many facts to show that in most epidemic diseases infection by fomites, though it exists, is ordinarily a very minor matter, Dr. Doty lays great stress on carrier and ambulant cases and the importance of detecting and isolating them. His views on this matter will meet with general acceptance, although the practicability of some of the suggestions made—for example, the routine daily examination of the throat of every school child—is open to question. When dealing with the practical work of port sanitation Dr. Doty has much sound advice to give. He insists, and rightly, that on vessels coming from ports which are technically infected the preventive measures necessary in the case of the first-class passengers or the principal officers of the ship are of a different order from those required where the steerage passengers or crew are concerned. The distinction should not, however, be carried too far. Dr. Doty tells us that "from one of the vessels arriving at New York after a voyage of 14 days from Naples were removed to quarantine six steerage passengers who had applied for treatment for minor affections during the voyage. None of these had had intestinal trouble, and all were apparently well on arrival, but were transferred as a matter of further inspection. After this group had been at quarantine for two days some were given two grains of calomel at bed-time and the next day a full dose of saline cathartic. The following day one of this number was in a condition of collapse and died within 24 hours. The autopsy did not reveal the cause of death, but the bacteriological examination of the intestinal contents furnished prompt evidence of cholera, which was subsequently confirmed by an exhaustive bacteriological examination. The brisk cathartic was undoubtedly the agent which called forth the activity of the organism." Steerage passengers may be inclined to ask whether the protection of the United States from cholera carriers cannot be effected by milder methods.

Much stress is laid on the importance of preventive measures, especially those against cholera and plague, being taken at the port of departure rather than at the port of arrival, and also on the necessity of conscientious and methodical work by ships' surgeons during the voyage. Such questions as these will no doubt be considered at the International Sanitary Conference, which is now sitting, and we may expect that some of the views which Dr. Doty holds will be developed in future international agreements. The recommendations for plague prevention on the whole coincide with British methods. The author considers that, subject to proper inspection, there is no reason for any detention of passengers or crew, or measures of rat destruction, if there is no sickness on arrival and the vessel has been at least eight days in transit from the infected port. He recommends caution in accepting the view that plague transmission is solely a matter of the plague-infected rat and associated fleas. All attempts to destroy rats on suspicion of their being plague-infected should be thorough if they are to be of any use. The escape of rats during unloading of cargo must be prevented, and complete destruction of rats in the empty vessel—preferably

by sulphur dioxide—must be secured, all dead rats being removed. The final chapter of the book gives a useful account of different mosquitoes associated with disease, including some personal observations by the author on the breeding places of Culex solicitans, the stripe-legged mosquito, which is said to hibernate in the egg, not as the winged insect. The eggs are laid in the soft ground of the swamp land of the Atlantic coast, and apparently the only practical method of their extermination is general land drainage.

Diseases of the Nose and Throat, comprising Affections of the Trachea and Œsophagus. By STCLAIR THOMSON, M.D. Lond., F.R.C.P. Lond., F.R.C.S. Eng., Physician for Diseases of the Throat and Professor of Laryngology in King's College Hospital. With Illustrations. London: Cassell and Co., Limited. 1911. Pp. 791. Price 25*s.*

Dr. StClair Thomson has enriched the literature relating to the diseases of the nose and the throat by embodying in a text-book the conclusions and results of his own experience. That experience, covering some score of years of special practice, is enhanced by a long period of experience gained in general practice. This latter experience, as Dr. Thomson very truly remarks in the preface to his work, has not only saved him from taking too narrow and too mechanical a view of the diseases of the air-passages, but has also helped him to realise their increasing importance in everyday work, and has enabled him to supply such information and assistance as a practitioner is likely to require.

The volume contains close upon 800 pages of closely printed matter. It is divided into 11 parts. The first part is introductory and includes a chapter on the Special Conditions and Dangers of Operations. It is a chapter that should be read, not only by senior students, but also by practitioners before undertaking operations upon the nose and throat. In discussing the "after-results" and the "insufficient or excessive removal of tissue" Dr. Thomson corroborates some of the remarks made recently by ourselves in an annotation on adenoids and tonsils (THE LANCET, Nov. 4th, 1911, p. 1284). The first five parts of the volume deal with diseases of the nose, of the accessory sinuses, of the naso-pharynx, and of the pharynx and tonsils, and form a *résumé* of accepted knowledge reinforced by the lessons of long practice. Part VI. is devoted to diseases of the larynx. The diseases of the trachea and the œsophagus, in view of the progress made in the direct examination of these regions, naturally receive separate consideration. The chronic infective diseases of the upper air-passages are dealt with together. The remaining three parts are devoted respectively to acute specific fevers in relation to the nose and throat, to the nose and throat in some general affections, and to some operations. Dr. Thomson, whilst keeping in mind that many operative measures should be entrusted to the hands of the man of special experience, still has thought it well to describe them with some fulness, indicating those that fall within a more general scope, and pointing out others that are fraught with particular danger or require exceptional skill. A complete account of the anatomy and physiology of the regions studied has not been attempted, but the space has been given up to the clinical and pathological bearings. The book is illustrated with 18 plates, many of which are coloured, and 294 figures in the text. At the end of the volume will be found a large number of useful formulæ.

The author tells us in his preface that in writing the book he has striven to keep two things constantly in mind: one, that it should serve as a guide to senior students; and the other, that it should prove a volume of ready reference to those engaged in the exercise of their profession. By the senior student the volume will be found to be more than sufficient for his immediate purposes, and by the practitioner, with the aid of the excellent index prepared by Mr. Archibald Clarke, the volume will be found to be one of ready reference. In it the practitioner will find a comprehensive study of the whole subject that will help him to determine what is amiss with his patient, what he himself can do for the patient, and what is the most he can expect from the assistance of the specialist.

Practical Cystoscopy and the Diagnosis of Surgical Diseases of the Kidney and Urinary Bladder. By PAUL M. PILCHER, A.M., M.D., Consulting Surgeon to the Eastern Long Island Hospital; late Surgeon to the German, Leney, and Samaritan Hospitals of Brooklyn, &c. With 233 illustrations, 29 of them being in colours. London and Philadelphia: W. B. Saunders Company. 1911. Pp. 398. Price 24*s.* net.

Cystoscopy as Adjuvant in Surgery, with an Atlas of Cystoscopic Views and Concomitant Text for Physicians and Students. By Staff-Surgeon Dr. O. RUMPEL, Lecturer in Surgery at the University of Berlin. Only authorised English translation by P. W. SHEDD, M.D. New York. With 85 illustrations in colour on 36 plates and 22 textual figures. London: Rebman, Limited; New York: Rebman Company. Pp. 131. Price 42*s.* net.

THE value of the cystoscope in the accurate diagnosis of diseases of the bladder and kidneys is definitely shown by the number of works that have been recently published describing the process of using the cystoscope and detailing the conditions observed. Dr. Pilcher's work is probably the largest and most complete book on the subject which has appeared, and it deals systematically with all parts of the subject. It commences with an account of the indications for cystoscopy, and some cases are quoted showing its value. Then follows a description of the various types of cystoscopes, with a discussion of their relative merits, the author expressing his preference for the Otis examining cystoscope. The mode of preparation of the patient and of conducting a cystoscopic examination are then described. With regard to anæsthesia, Dr. Pilcher holds that in the great majority of cases no anæsthetic is necessary; and when one is required he considers that a local anæsthetic is sufficient. A useful chapter is that devoted to a description of what is seen in the bladder, and the variations which may occur in health are described, and then those which occur in disease. The methods of investigating the functional activity of the kidneys are discussed, and the author prefers the indigo-carmine test, as ureteral catheterisation need not be practised for its efficient working. The next section deals with the diseases of the kidneys as revealed by the cystoscope, and a chapter on the therapeutic uses of the instrument follows. The book contains a large number of excellent illustrations, and many of these are coloured.

The use of Staff-Surgeon Rumpel's atlas will be confined to a comparatively small section of surgeons, and yet its value is very high in the diagnosis of morbid conditions of the bladder and kidneys. The use of the cystoscope is not at all difficult, as to some extent is made apparent in Dr. Pilcher's work just noticed, but much experience is needed to interpret correctly the cystoscopic appearance, and a good atlas such as this will greatly assist the inexperienced. The text of this volume will doubtless prove of use, but the most valuable part is certainly the large series of coloured illustrations. These have been carefully drawn and excellently reproduced. The author describes and discusses the methods of estimating the renal function; he considers that the phloridzin test has, despite its reliability, the disadvantage of requiring a certain delicacy in execution which impairs its value. He looks upon bi-ureteral catheterisation as the most thorough and reliable method of comparing the function of the two kidneys, and in his

opinion no method of determining renal function surpasses cryoscopy in the accuracy of its results.

Sémiologie Réelle des Sections Totales des Nerfs Mixtes Périphériques. By HENRI CLAUDE and STEPHEN CHAUVET. Paris: A. Maloine. 1911. Pp. 95. Price 4 francs.

THIS short monograph is devoted to a consideration of the symptomatology of complete transverse lesions of peripheral nerves, viewed solely from the standpoint of clinical examination. It contains little that is new. The authors remark in their preface that with the exception of the researches of Head, Rivers, and Sherren,[1] and the work of Babinski and Tournay, the clinical aspect of lesions of mixed peripheral nerves has hitherto been neglected; and they give in this brochure the results of their own examination of various cases. In some respects their methods of examination appear to be rather inadequate, notably as regards localisation, the compass test, sense of position, and the temperature sense. On the other hand, they bring forward data in regard to vaso-motor and osseous changes subsequent to complete transverse lesions of mixed nerves, and this part of the monograph will repay perusal.

Die Therapie der Magen- und Darmerkrankungen. Von Sanitätsrat Dr. CARL WEGELE. Fourth revised edition. With 11 illustrations. Jena: Gustav Fischer. 1911. Pp. 458. Price, paper, 7.50 marks; bound, 8.50 marks.

DISORDERS of the stomach and intestines of all degrees of severity are so common and are responsible for so much discomfort and ill-health that a practical work on their treatment is likely to serve a very useful purpose. The appearance of a fourth edition of Dr. Carl Wegele's book suggests that its utility has received recognition, and after a careful examination of its contents we can affirm that it deals in an exhaustive and instructive manner with the treatment of these conditions. The author has evidently a wide and up-to-date knowledge of the literature of the subject, to which numerous references are made on nearly every page, and he has obviously in addition a thorough practical experience, so that his recommendations have usually a personal basis and are given with all necessary details. Prescriptions are printed in full, and any procedures advised are described at length.

The book is divided into two sections. The first deals with the general treatment of digestive disorders; the second with the special treatment of individual conditions. In the first section considerations of diet are carefully examined. General directions are given in regard to the various factors influencing the digestibility of foods, and then the individual articles of diet are categorically considered, their heat value and nutritive qualities being especially dealt with. The various physical methods of treatment, including lavage, massage, the various forms of enemata, electrical and bath procedures are then carefully reviewed, with their indications and contra-indications. A long chapter is devoted to the modes of action and uses of the various medicinal substances employed in the treatment of gastro-intestinal conditions. This chapter, which is based upon an exhaustive study of the literature, is one of the most interesting and useful features of the book, since it contains information not usually to be found in text-books, but only in monographs. Another chapter deals with the indications for operative interference in diseases of the alimentary tract, and gives numerous references to the statistics of the more important operations in appraising their value.

In the second section the individual diseases and disorders of the stomach and intestines are classified, and their treatment is fully considered. The classification is simple and comprehensive, while the directions in regard to treatment are exhaustive. At the same time Dr. Wegele is careful to indicate his own preference in regard to the various methods described. In each case carefully selected diets are given. The description of the treatment of gastric ulcer is worthy of mention as an admirable review of the various methods at present employed. Other conditions of which the accounts given are noteworthy are gastric atony and its consequences, the various disorders of gastric secretion, neuroses of the stomach and intestines, chronic constipation, intestinal auto-intoxication, and appendicitis. The arguments for early operation in the last-mentioned condition are set out, and the general indications for surgical treatment are also reviewed.

Dr. Wegele's book is an important addition to the literature of digestive diseases, and a valuable work of reference. It is thoroughly modern, and contains more references to English and American monographs and papers than is usual in German text-books. In this connexion it is interesting to notice that Dr. Wegele remarks upon the striking frequency of duodenal ulcer in England and America, as judged by the statistics of the surgeons of those countries. The book is of convenient size, well printed, and easy of reference. It contains an index of authorities as well as one of subjects.

Racial Decay: A Compilation of Evidence from World Sources. By OCTAVIUS CHARLES BEALE. London: A. C. Fifield; Sydney: Angus and Robertson, Limited. 1911. Pp. 439. Price 5*s.* net.

Mr. Beale may be known to our readers as the Royal Commissioner appointed under the Australian Government to inquire into quack medicines. He was appointed in 1906, and this inquiry was the outcome of a previous inquiry in 1903 in New South Wales regarding the decline in the birth-rate and infant mortality. The present volume, although not official as was the former book, is an extended investigation of Mr. Beale's work begun as a Royal Commissioner, and deals with one of the most important problems of these times—namely, racial decay and the causes which are leading thereto.

The work is arranged in what may be called a tabular form—i.e., extracts from various books, pamphlets, statistical publications, and Government reports are given, with a running commentary by Mr. Beale. Division I., which is called the "Genesis of the Carcinoma," treats of Malthus's works and the expansion thereof by ill-educated reformers. The "carcinoma" is the wastage of child life, either prenatal, as by abortion or prevention of conception, or postnatal, as by the appalling mortality at early ages of child workers in factories, such as used to occur in Manchester some 60 years ago. Division I. therefore also deals with the Ten Hours Bill of 1847 and the bitter opposition of the factory owners' representatives.

The remainder of the work deals with depopulation in various countries, France being taken first, because in that country the evidence of depopulation is most marked. But the plague is widespread in other countries, too notably in our own, and the gist of Mr. Beale's book is that the practices of the prevention of conception, or when this fails, of procuring abortion, are affecting for the worse nearly all the great European Powers. Medical men are aware that racial mischief is being done, and our readers cannot fail to remember the series of articles upon Quacks and Abortion published in these columns in 1898 and 1899. In dealing with the pathological consequences of the practices above referred to, is grim reading. Mr. Beale and the authorities whom he quotes possibly protest too much in attributing such an appalling train of diseases and symptoms to the practice

of prevention. Dr. Bergeret's remarks as quoted by Mr. Beale read somewhat like the advertisements of self-abuse quacks.

The evil is widespread, the United States, and to a very serious extent Australia and New Zealand, are affected. One very notable fact is that the decline in the birth-rate is most marked among the upper classes—that is to say, among those whose circumstances are such that if they had children such children would stand a better chance in the race of life. This fact is very significant. It is nothing new; the same situation arose in the Roman Empire and was exposed in fiery denunciation by Juvenal:—

> Sed jacet aurato vix ulla puerpera lecto.
> Tantum artes hujus, tantum medicamina possunt,
> Quae steriles facit, atque homines in ventre necandos
> Conducit. (Sat. vi. 593 et seq.)

Social Reform is the cry of the present day, but the Governments of all countries take but little notice of what is perhaps the most prominent evil of the times. The trade in abortefacients, real or pretended, and in preventives is naked and unashamed, while the press in many cases lends aid in enlarging the market. It is true that a people cannot be made moral by Act of Parliament, but Parliament could at least see that incentives to immorality are not allowed the liberty of public advertisement.

Leitfaden der Akustik für Ohrenärzte. By Dr. M. TH. EDELMANN, Prof. h.c. der Kgl. Techn. Hochschule, München. With 80 illustrations and a portrait. Berlin: S. Karger. 1911. Pp. 118. Price 4 marks.

Professor Edelmann opens his thesis with a description, freely illustrated, of the various forms of vibration, proceeding to demonstrate by diagram many of these points. He next proceeds by investigation and demonstration to elucidate the principles of the strength and the height of tones, and the intervals between two tones, this being accompanied by a table showing the numerical vibrations of various notes. He then illustrates and discusses the effect of two tones or notes produced simultaneously, and shows the effects of their interfering with each other.

Tuning-forks next come under review. Afterwards the overtones of the tuning-forks which possess them and the effect of tuning-forks without overtones are discussed. A full description follows of Bezold's tuning-forks, and the whistles or pipes for the improvement of which Professor Edelmann has already become so well known. Then is given information about sound-plates and their employment as a means of comparison with tuning-forks, a short note on König's tubes and Schültze's monochord, and a description of the continuous tone series with the resonators. He also deals with sirens and all other forms of sound-producers. On p. 98 the author discusses the early acoustic investigations, and concludes with a description of a large model of the hearing apparatus demonstrating the mechanism of hearing.

This production of an erudite man is of great value, and we trust that it will find a translator, so that material of such importance shall not be confined to those able to read German sufficiently to enable them to derive full benefit from its perusal. It is not too much to say that nowhere else is there a better description of the acoustics as interesting the aural surgeon.

The portrait referred to in the title is a portrait of the late Professor Bezold, to whom the book is dedicated.

Health and Disease. By W. LESLIE MACKENZIE, M.A., M.D. Aberd., Medical Member of the Local Government Board for Scotland. London: Williams and Norgate. 1911. Pp. 244. Price 1*s.* net.

THIS volume, which Dr. Leslie Mackenzie has contributed to the attractive little series of shilling books in the "Home University Library of Modern Knowledge," comprises 16 short essays on various topics, such as What is health? death-rates and their interpretation; how antitoxins are produced and prepared; and a discussion of the tubercular diathesis; disease and destitution. He concludes by discussing insurance methods of preventing sickness and the evolution of the health movement. The essays will, we are sure, be read with pleasure and profit by a considerable public. Though the subjects are somewhat disjointed there runs throughout the book a strong note of faith in the improvement of the race by attention to individual and to public health, as well as the author's sense of the greatness of the duties which the medical profession is called on to fulfil both in preventing and curing disease. Dr. Mackenzie's method is essentially that of the preacher, and most of his medical readers will have their own reservations to make on the dogmas which he confidently expounds and on the "heresies"—such as belief in hereditary disposition to disease—which he regards as anathema. Some, if so unhappily and modestly constituted, may even find that the author's exaltation of the medicine of to-day, and his prophecies of its achievements to-morrow, leave them a little uncomfortable; they could wish they had been reading the writings of a layman about their profession rather than the views which a distinguished member of their profession presents in a volume which we feel confident will appeal strongly to laymen. The lay reader will find it difficult to resist being carried away by Dr. Mackenzie's zeal, but in doing so may be considerably disquieted at the possible issues of development on such lines as the author would seem to forecast. But both classes of critics will no doubt be the better for a shaking, and all who have not become cynical past redemption will find encouragement and enjoyment in Dr. Mackenzie's sermons.

LIBRARY TABLE.

Transactions of the Royal Academy of Medicine in Ireland. Vol. XXIX. Edited by J. ALFRED SCOTT, M.A., M.D. Dub., F.R.C.S. Irel., General Secretary, Professor of Physiology, Royal College of Surgeons in Ireland. Dublin: John Falconer; London: Baillière, Tindall, and Cox; Edinburgh: James Boyd; Bristol: John Wright and Co. 1911.—Besides the lists of officers, fellows, members, and associates, the rules, the annual report, and the treasurer's report, this volume contains the papers that have been read before the Academy in its respective sections of Medicine, Surgery, Obstetrics, Pathology, State Medicine, and Anatomy and Physiology. A considerable proportion of these have already appeared in our columns, either in full or as reported in the Academy's proceedings. They will prove of interest in their collected form.

School Life. Edited by T. N. KELYNACK, M.D. Vict., M.R.C.P. Lond. London: Charles H. Kelly. 1911. Pp. 160. Price, limp cloth, 1*s.* net; cloth boards, 1*s.* 6*d.* net.—This is the third of the series of National Health Manuals, the object of which is to provide in concise language and compact form essential facts, and to indicate in simple words the underlying principles upon which the preservation of health and the prevention of disease are based. The chapters in this book are by different writers, and each writer has been granted a free hand in dealing with his subject. They are as follows: School Life, by the Editor; Characteristics of School Children, by Mr. A. S. Arkle; the Hygiene of the School, by Dr. Charles Porter; Medical Inspection of the School Child, by Mr. J. C. Bridge; the School Child Worker, by Dr. D. M. Taylor; the Physical Education of the School Child, by Dr. F. Barrie Lambert; the Personal Hygiene of the School Girl, by Dr. Myra Mackenzie; the Personal Hygiene of the School Boy, by Dr. J. O. Symes; Dental Condition in School Children, by Mr. C. Edward Wallis; Mentally Defective Children, by Dr.

C. P. Lapage; Physically Defective Children, by Dr. H. H. Rayner; the School Child and Citizenship, by Dr. A. D. Edwards. There is for each chapter an appendix containing a bibliography. The book covers all aspects of the subject, and will be of use to school teachers, inspectors, parents, and to medical men and others especially interested in the school problem.

Quackery (Quack Remedies and Quack Practice) and Medical Law Reform: A Plea for a Royal Commission. By HENRY SEWILL. London: P. S. King and Son. 1911. Pp. 32. Price 6*d.* net.—This pamphlet has been printed in order that it may be widely distributed to open the eyes of the public to the nefarious doings of quack medicine mongers. The author shows in the preface by specific cases the difficulty of obtaining aid from the lay press. The work is a reprint from *Vanity Fair* of articles on "Secret" Remedies, Quackery and the Ethics of Journalism, Quackery, Quackery for Women, and Medical Law Reform and Quackery. It is a good one for its purpose in all respects but one—that sixpence is a good deal to give for a pamphlet for general presentation; and although it is stated that in quantities of a dozen and upwards it may be obtained at reduced rates on application to the publishers, the rates will have to be very materially reduced before any large number will be purchased for general distribution.

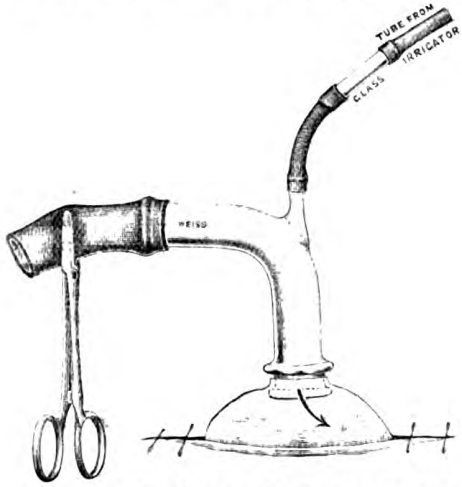
JOURNALS AND MAGAZINES.

Quarterly Journal of Experimental Physiology. Edited by E. A. SCHÄFER, F. GOTCH, W. D. HALLIBURTON, C. S. SHERRINGTON, E. H. STARLING, and A. D. WALLER. Vol. IV., No. 3, Oct. 24th, 1911. London: Charles Griffin and Co. Price 6*s.*—In this number will be found the following articles:—1. R. A. Chisolm: On the Size and Growth of the Blood in Tame Rats. Although the title of R. A. Chisolm's paper looks a little odd, its author's object was to determine the total amount of hæmoglobin, the number of red cells, and the blood volume of normal rats preliminary to an inquiry into the influence of transplanted malignant tumours on the constitution of the blood. The number of red cells is 9,000,000 per cubic millimetre. The other details will be found in the summary. 2. W. Mulder: Analysis of the Rotation-Reflex in the Frog. The name of W. Mulder is indelibly associated with Utrecht. The rotation-reflex referred to is that shown by a frog when placed on a horizontal turning disc with its head towards the disc edge. The head makes a reflex movement which is directed against the sense of motion of the disc, and is due to stimulation of the labyrinth by the circular acceleration. The author finds that the speed of the reflex is directly proportional to the amount of the stimulus, but the relation is not logarithmic, as is the case with sensations. 3. Jasper Halpenny and John A. Gunn: Note on Extirpation of Thyroid Gland in Monkeys. The note on the thyroid derives its interest from the experiments having been made in monkeys, as the authors thought it advisable, as a preliminary to other work on the thyroids, to repeat the experiment of simple extirpation in monkeys. It is to be noted that some of the experiments were done in Manitoba during the depth of winter, when the temperature during the night must frequently have fallen very low. 4. H. M. Vernon and H. R. Stolz: The Influence of Forced Breathing and of Oxygen on Athletic Performance. One of the authors of the fourth article (H. R. Stolz)—is a trained athlete, and the results of running a measured distance (387 yards) 20 times under different conditions are given in a number of tables. The authors arrive at the conclusion that deep breathing or oxygen breathing cannot augment the running powers of a well-trained and unfatigued man for distances of a quarter of a mile or less. 5. Sutherland Simpson: Improved Technique in the use of Schäfer's Frog-Heart Plethysmograph. This paper is of interest only to physiologists. 6. Sutherland Simpson and Andrew Hunter: The Possible Vicarious Relationship between the Pituitary and Thyroid Glands. The paper deals with the authors' observations on sheep and lambs. Removal of the thyroid does not lead to the appearance of iodine in the pituitary, and it would seem that in thyroid insufficiency the pituitary does not vicariously take on the function of the thyroid. 7. T. Graham Brown: Studies in the Physiology of the Nervous System—VIII., Neural Balance and Reflex Reversal, with a Note on Progression in the Decerebrate Guinea-pig. T. Graham Brown's eighth contribution to his Studies in the Physiology of the Nervous System deals with a highly technical physiological subject, the reversal of reflex action. 8. L. Bull: On the Simultaneous Record of the Phono- and Electro-cardiogram. L. Bull's paper is one of a highly technical character, and will interest physiologists. 9. R. A. Krause: On the Urine of Women under Normal Conditions, with Special Reference to the Presence of Creatin. R. A. Krause finds that creatin is present in the urine of women immediately after menstruation; it may or may not be present during the intermenstrual period. It is present in the urine of women during pregnancy. Observations on a bitch during the œstrous and anœstrous periods confirm the existence of a correlation between creatinuria and the female sexual cycle.

The Dublin Journal of Medical Science.—In the November issue is published a paper by Dr. J. Boyd Barrett on Some Surgical Symptoms in Children, in which he deals specially with the phenomena accompanying hypertrophic stenosis of the pylorus and infection of the urinary tract. He notes that thread-worms in the appendix may give rise to a condition simulating appendicitis. Dr. S. F. A. Charles discusses chorea and its treatment, strongly recommending trional for the latter purpose.

The Birmingham Medical Review.—The treatment of aneurysm is discussed by Dr. T. Stacey Wilson in the November number of this magazine. He has had favourable results from careful application of the "old-fashioned and ordinary" method of treatment—rest and full doses of iodide of potassium, and believes that the mode of action of the remedy is by increasing the resisting power of the wall of the sac. Dr. K. Douglas Wilkinson records a case of heart-block in a young woman, aged 24 years, and discusses the pathology of the condition.

ERRATUM.—In our review of the new edition of "Diseases of the Lungs," by Sir R. Douglas Powell and Dr. P. Horton-Smith Hartley, an error has occurred in stating that the two plates illustrating Curschmann's spirals appeared in the previous edition of this book. Both the figures on this plate, as well as the one facing it in the text and the plate showing casts in plastic bronchitis, are from drawings specially prepared for this edition.



New Inventions.

AN IMPROVED COLOTOMY TUBE.

THE paramount importance of evacuating the septic and highly toxic contents of the bowel with the least possible delay in cases of acute obstruction has long been recognised. Unfortunately, this is not always an easy matter, and after fixing the ordinary colotomy tube of Paul's pattern into the gut attempts to empty the bowel are confined to the giving of aperients by the mouth, and more recently the administration of eserine subcutaneously to stimulate peristalsis. As, however, vomiting may continue for some hours or even days after the operation aperients are frequently of little use. The

most effective and quickest method of emptying the bowel is to wash out the contents by means of an enema; this, however, cannot be done with the colotomy tube at present in use. On several occasions I have tried to do this by making a small hole in the large rubber escape tube used to carry off the bowel contents and introducing fluids while the tube is clamped below the hole. This has proved unsatisfactory, as leakage occurs subsequently through the hole and the tube is rendered useless in future.

Some months ago Messrs. Weiss and Son made to my pattern a colotomy tube (see illustration) which avoids these drawbacks and allows the bowel to be flushed without inconvenience. The tube differs from the one in general use in the fact that a small short arm is inset into the convexity of

the curve, so that it has the same direction as the limb of the tube which is inserted into the bowel. When in use a small piece of drainage tube about six inches long is fitted on to the short arm. After the tube is fastened into the bowel the end of the drainage tube will project above the dressings, and must be secured to prevent the escape of bowel contents; this may be done with a pair of clip forceps or a safety pin attached to the binder or the tube may be tied in a simple knot. After the first gush of fæcal material has passed the interior of the bowel can be washed out by means of a douche can or an enema syringe, the fluid being led through the small rubber tube into the interior of the colotomy tube. The large escape tube is flushed out and then clamped, after which the fluid enters the bowel. In this way enemata can be given at short intervals without disturbing or soiling the dressings. The ordinary enemata can be employed, but if an irritant such as turpentine is used only half the usual strength should be given on account of the inflamed state of the bowel.

Another great advantage is that after the bowel is cleared, which can be done usually in about six hours, fluids such as warm saline can be given in the same manner as is employed in septic peritonitis. It is rapidly absorbed and is useful in replacing the amount of fluid lost by the previous vomiting. If the vomiting has been present for some days another element antagonistic to the patient has to be reckoned with, namely, actual starvation, as nothing taken by the mouth has been retained in the stomach; for this reason it is a good plan to add to the saline sufficient glucose to make a 2 per cent solution. This can be absorbed directly into the blood and used as a food.

I have used these tubes on more than a dozen cases and find them a great advance on the old ones, which serve merely as an outlet for the bowel contents. The tubes are made in four sizes, ranging in diameter from half an inch to an inch and a quarter.

DUNCAN C. L. FITZWILLIAMS, Ch.M. Edin.,
Grosvenor-street, W. F.R.C.S. Eng. and Edin.

ASSOCIATION OF CERTIFYING FACTORY SURGEONS.—The annual dinner of this association will be held at the Trocadero Restaurant, London, on Friday next, Dec. 8th, at 7.30 P.M. Communications should be addressed to the secretary, 16, John Dalton-street, Manchester.

CENTRAL MIDWIVES BOARD.

A MEETING of the Central Midwives Board was held at Caxton House, Westminster, on Nov. 23rd, with Sir FRANCIS CHAMPNEYS in the chair.

The following letter was considered from the clerk of the Privy Council as to the power of the local supervising authority to make a rule prohibiting a midwife from laying out a dead body:—

Privy Council Office, 19th October, 1911.

To the Secretary, Central Midwives Board.

SIR,—Referring to your letter of the 13th instant enclosing a copy of a letter from the town clerk of St. Helens as to the power of the local supervising authority to make a rule prohibiting a midwife from laying out a dead body, I have to point out, for the information of the Central Midwives Board, that it is not suggested that the local supervising authority has any authority under the Midwives Act, 1902, to make such a rule, but that Rule E, 17 (b) of the Board's rules, as finally drawn, was intended to save any right possessed by the councils of counties or county boroughs under their general statutory powers to make a rule on the subject, it being better that there should be a general rule in the matter, rather than that it should be left to the discretion of the authority in particular cases.

I am, Sir, your obedient servant,
(Signed) ALMERIC FITZROY,
The Clerk of the Council.

The Board directed that a copy of the letter from the clerk of the Council be forwarded to the town clerk of St. Helens.

A letter was considered from the superintendent of the Gloucester District Nurses' Home, inquiring as to whether a midwife should undertake a case when she believes it would be better for the patient to engage a medical man, and as to her duty to notify a stillbirth when engaged as a maternity nurse under a medical man. The Board decided that the reply should be: (*a*) That the question of whether a midwife should undertake a case or not is outside the rules, and must be decided by the exercise of the ordinary judgment of a prudent midwife. (*b*) That a midwife acting as a maternity nurse under the direction of a qualified medical practitioner is not bound to notify a stillbirth under Rule E, 21.

A letter was considered from Dr. W. E. Fothergill, of Manchester, one of the Board's examiners, as to lengthening and raising the standard of training, and a letter was considered from Mr. E. Sergeant, county medical officer for Lancashire, to the same effect. The Board decided that the letters of Dr. Fothergill and Mr. Sergeant be noted for consideration at the next revision of the rules.

A letter was considered from Dr. J. M. Cowie, medical officer of health of Burton-on-Trent, inquiring as to the course to be adopted with regard to midwives who can neither read nor write, or who are incapable of learning to take or record pulse and temperature. The Board directed that it be pointed out to Dr. Cowie that it lies with the local supervising authority to take action in the first instance against midwives who are unable to comply with the rules of the Board, and that the Board would deal with any midwife against whom the authority had found a *primâ-facie* case of malpractice, negligence, or misconduct.

A letter was read from the superintendent of the Cornwall County Nursing Association, inquiring whether a midwife may attend maternity cases and nurse cases of enteric fever at the same time. The Board decided that the superintendent of the Cornwall County Nursing Association should be referred to Rule E, 5, which runs as follows:

Whenever a midwife has been in attendance upon a patient suffering from puerperal fevers, or from any other illness supposed to be infectious, she must disinfect herself and all her instruments and other appliances, to the satisfaction of the local supervising authority, and must have her clothing thoroughly disinfected before going to another labour. Unless otherwise directed by the local supervising authority, all washable clothing should be boiled, and other clothing should be sent to be disinfected by the local sanitary authority.

A letter was considered from the clerk of the Aberdare urban district council forwarding a copy of a resolution passed by the council expressing the opinion that a period of 24 hours is too short a quarantine for a midwife who has been attending on virulent cases of puerperal fever. The Board directed that the attention of the clerk of the Aberdare urban district council be called to the terms of Rule F, 2, which prescribes the procedure in cases where it is found necessary to suspend a midwife for a longer period than 24 hours.

A letter from Dr. Comyns Berkeley, obstetric physician, Middlesex Hospital, on behalf of the weekly board of the hospital, with regard to a complaint made by a certified midwife of the inadequacy of the training given at the hospital, was considered, and the Board decided that all further action should be left in the hands of the chairman.

THE LANCET.

LONDON: SATURDAY, DECEMBER 2, 1911.

The National Insurance Bill.

THE position of the medical profession under the National Insurance Bill, now entering upon the report stage, remains an exceedingly anxious one. We publish elsewhere in this issue of THE LANCET accounts of important meetings of medical men held in Scotland and Ireland, as well as a *résumé* of the proceedings at the special meeting of Representatives of the British Medical Association which took place on Thursday and Friday of last week. From the evidence fully supplied by the debates and resulting resolutions at these meetings it stands out clearly that the profession as a whole mistrust the measure deeply, and at this late hour in the proceedings the fact can but strike us all as ominous. The meeting of Representatives of the British Medical Association, not without real opposition to some of the views eventually adopted, registered resolutions implying a decision to work under the Bill if the six cardinal points were granted. The view of the Representatives has been embodied in a memorandum and forwarded to the Chancellor of the Exchequer, who, in response to further representations of the Association, has put down certain amendments, of which a summary will be found in our Parliamentary report. In Scotland the temper of professional opinion is even more adverse to the measure, while Ireland desires, on the whole, to be brought into line with England, Scotland, and Wales by an extension of the medical benefits under the Bill to that country upon the same lines as those demanded by the profession elsewhere. We publish this week no individual opinions upon the Bill, for although some of our numerous correspondents have brought forward interesting points of criticism, these are for the most part dealt with in favourable or unfavourable sense by the resolutions of large meetings. That is to say, that in these many but separate communications the same message of deep anxiety can be traced. The solidarity of the medical profession remains thus what it has always been—viz., a general distrust of a scheme, however nobly intended and however useful to the material interests of medicine in some directions—which proposes to revolutionise the whole professional life of a large number of medical men without any proper time having been given to the comprehension of the details of that life, of its real hardships, its fine compensations, or its great ideals.

At the session of the General Medical Council which was opened on Tuesday last, Sir DONALD MACALISTER delivered a Presidential address which will be read in our columns with anxious attention. The General Medical Council, as is well known, without being committed to any final expression of opinion on the National Insurance Bill as a piece of legislation, has viewed with deep apprehension the possible effect upon medical education of a radical disturbance of the conditions of practice which may lead to a profound alteration of medical life. The fear of the General Medical Council is that if the conditions of practice under the measure should prove highly distasteful to a large number of practitioners, the result will be an increase in that shrinkage of candidates for entrance to the medical profession which has already given the Council anxious thought. The Council, especially during the last decade, has worked with unremitting zeal at the arduous task of raising the medical education of this country to a high level, and of keeping it at that level. The difficulties arising out of an overcrowded educational curriculum, which to some extent are directly related to the maintenance of a high standard, are now being boldly faced, but the more the many questions involved are closely looked into, the more clear it becomes that modern preparation for the life of a medical practitioner must be a very strenuous matter for both teacher and taught. A long time and much money will have to be spent by the student of the future in the acquisition of a familiarity with the general groundwork of our inclusive science sufficiently intimate to warrant the General Medical Council in placing him upon the statutory roll of the profession. The young man on learning this, and on learning also that the conditions under which he will be expected to pursue his avocation do not correspond with so strict and expensive a guarding of the portal, will not enter the ranks of medicine. We ask, then, what course is to be pursued? To suggest in these days that the body entrusted with the management of the professional education of our medical students should deliberately lower its due scientific standard is unthinkable. To carry on the business of insuring the health of the community with an inadequate supply of practitioners is equally hard to imagine. The Insurance Commissioners may find that they have here a veritable problem.

The names of the Insurance Commissioners will probably not serve to allay the legitimate misgivings of the medical profession. If the profession decides to attempt to carry out the duties that are proposed to be laid upon it, it will be of the utmost importance that the Commissioners should form a very strong, experienced, and sympathetic body. The medical men will require protection all along the line, for while they have apparently been invited to join the scheme first and adjust their quarrel with it later, their representation on the local authoritative bodies, where the discussions are sure to occur, is extremely small, though we understand that the Chancellor of the Exchequer proposes to remedy this default in some degree. The Government, finance, trade, and labour, and the interests of approved societies are represented by Mr. J. D. STUART SIM, Mr. JOHN BRADBURY, Mr. D. J. SHACKLETON, Miss MONA WILSON, and Mr. LISTER STEAD. The chairman, Sir ROBERT MORANT, by far the strongest Commissioner, may be implicitly trusted to see fair-play and be fairly assumed to be conversant with, and sympathetic towards, professional ideals. The name of the medical Commissioner has not been announced as we go to press. A heavy responsibility will devolve upon him, for the suggested further amendments to the Bill cannot, alas, be said to remove all professional opposition.

The Anatomy of Spinal Puncture.

ALTHOUGH the technique of spinal puncture for introducing analgesic drugs has been carefully studied in this country the literature dealing with the anatomy of the parts involved affords few recent additions to our knowledge. The importance of an exact knowledge of the anatomy of the subarachnoid space and of the precise limits of the conus medullaris can hardly be over-rated. Early in the last century KEY and RETZIUS made some careful studies with regard to the former, and QUINCKE, GERSTENBERG, and HEIN, as well as PROPPING, have extended our knowledge. MAJENDIE'S experimental work upon the movements of the cerebro-spinal fluid is too well known to need comment, but when we find that much discrepancy of opinion persists both as to the site of election for puncture as well as to the causation of dangers immediate and post-operative, we are compelled to believe that the subject is still imperfectly understood. Dr. WILLIAM C. LUSK (in the *Annals of Surgery* for October) has published a statement of the results at which he has arrived after a careful series of dissections of the whole region involved. He has located the exact position at which the spinal cord terminates, and describes minutely the arrangement of the arachnoid membrane, the position of nerves and veins, as well as the conus itself, as regards their possible injury by the puncturing needle. The dissections of the arachnoid membrane convince him that any puncture undertaken between the conus and the cervical region must be attended with the greatest risk of penetrating the cord. In many dissections there were adhesions of the arachnoid membrane to the cord throughout more or less of its length, and Dr. LUSK concludes from this that "if cerebro-spinal fluid can be constantly drawn as a result of mesial puncture at or above the level of the conus, in many instances the substance of the cord must be traversed by the needle and the fluid taken from the anterior portion of the subarachnoid space." Puncture in the dorso-lumbar interspace in a certain proportion of cases results in damage to the cord, as some dissections revealed the fact that the arachnoid is not infrequently adherent to the posterior surface of the conus or cord.

REHN has shown experimentally that injury when associated with injection of such drugs as stovaine or tropacocaine leads to immediate death with medullary symptoms. The cases of death quoted by Dr. LUSK are of peculiar interest in this connexion, and deaths otherwise inexplicable become clear in their causation if considered in the light of his work. Puncture below the level of the conus involves an accurate acquaintance with the disposition of the nerve roots of the cauda equina. Although, as the dissections show, the distribution of the nerve roots in the arachnoid sac varies, yet their arrangement in relation to one another appears fairly uniform. It is pointed out that while most of the nerve roots fall away to the sides, the lowest sacral nerve roots occupy a mesial position, and so are rendered more liable to trauma. The not infrequent paralysis of the bladder and sphincters consecutive to lumbar puncture finds an explanation in this fact. Dr. LUSK deals carefully with the question of the sacral leverage, so important when the position of the patient at the time of puncture is considered, since in forward tilting of the pelvis, which exists in extreme lumbar flexion, the mesially placed sacral nerves will become taut and present posteriorly. Hence the pelvis must be prevented from any forward tilt, as the needle impinging upon a taut nerve root will impale it, while it will push a slack tissue aside without injury to it. The characters and arrangement of the cauda equina in these dissections are grouped into five varieties, and it is shown that even an escape of the cerebro-spinal fluid after puncture cannot in all cases be accepted as a proof that the point of the needle is not engaged in some nerve structure. The site of maximum safety for performing the lumbar puncture seems from the facts advanced to be the interval between the fourth and fifth lumbar vertebræ made mesially, while the lumbo-sacral space, we are told, is probably equally safe, but only second in order of desirability. Dr. LUSK elaborates the rules for the technique of the puncture, basing his conclusions upon his anatomical findings. He believes that a blunted needle is safer than a sharp one, and in most cases entrance a little to the side of the middle line avoids the tougher superficial structures and allows greater precision of touch than in the case of the central puncture. There can be little doubt that the arguments adduced and the admirable reproductions of photographs of the dissections will enable the workers in this field of surgery to understand with greater clearness the etiology of many of the dangerous and painful sequelæ which have been recorded as following the lumbar puncture. With this increased accuracy of their pathology it is not too much to expect that the present somewhat serious list of deaths and post-operative troubles may become materially curtailed.

The Cancer Cell.

THE problem of the origin of cancer has been attacked from time to time by numberless observers, and the solutions which have been put forward have been many. The manifestations of cancer are striking. From a small, hardly palpable beginning arises a mass of tissue which at last may assume such a size as to form no small proportion of the whole body in which it has arisen. For a while it may do little damage, but sooner or later, in most cases at least, there comes a time when by its mere bulk and its interference with the activity of some vital organ it makes clear its harmful influence, and at last, after months or years, it leads to the death of the body in which it has dwelt. The latest of the many attempts at the solution of the problem was made last month at the Royal College of Surgeons of England by Sir HENRY BUTLIN in two lectures, the latter of which we publish in the present issue of THE LANCET. We are sure that our readers will peruse these communications with the greatest interest, as the contribution to our prime surgical difficulty of one who has shown himself alike a profound thinker and a practical man.

The main phenomena of cancer are beyond dispute, but these phenomena are many as well as striking—their multiplicity is indicated by what we have said above—and therefore it is by no means easy to suggest a theory which will

explain them all. The theory which attributes the appearance of a malignant growth to the presence of a remnant of embryonic tissue was ingenious, but even if it served to explain somewhat the origin of the tumour it was incapable of giving a satisfactory explanation of the appearance of metastases. The idea that an external injury was responsible failed utterly in view of the fact that the vast majorities of injuries are not followed by any such tumour, though there can be little doubt, from the constant association of certain special injuries with malignant disease, that it is possible for a local injury to exert some predisposing influence. Every theory fails somewhere in the proof, and it may be truly said that at the present time no fully satisfactory explanation of the manifestations of cancer has been given. In the Bradshaw lecture at the Royal College of Surgeons of England delivered in November, 1905, Sir HENRY BUTLIN first broached his theory that the cancer cell is an independent organism, like many a protozoon; that it lives a life which is wholly independent and proper to itself, and that it lives in the body of the animal affected with the cancer, deriving its nourishment from its host and yet doing nothing to repay the host for the sustenance of which it robs him. In his recent lectures he has expanded the same idea as a result of the thought which he has devoted to the matter in the intervening period, and comes to the conclusion that the cancer cell is not merely like a parasite, but is a parasite, which has been formed from the very tissues of its host. In appearance the cancer cell remains so like the cells in which it first appears that there can be no doubt that it is indeed derived from a cell of the normal tissues. Yet how different are its functions now. At one time its sole aim was to serve the host of which it was a part, and for that it was ready to undergo the changes which are normal to such a living cell: but now it has suffered a subtle change; it is still in the likeness of a normal cell, yet it has ceased to take any care for the body, of which it had been long a part; its only aim is to grow and to reproduce itself, and it carries out these objects at the expense of the body to which it belonged. Sir HENRY BUTLIN would regard the cancer cell as an independent animal which is parasitic, and in every way manifests its parasitism, and he has called it the "unicellula cancri," being inclined to place it among the protozoa. No such brief summary will suffice to explain the author's views, and we urge our readers to follow the theory expounded in the luminous phrases and with the happy illustrations which characterise all that Sir HENRY BUTLIN writes. In the face of the exposition of that theory by one so highly gifted and so justified by a lifetime of experience, we must suspend our judgment if we do not feel ready to agree, while acknowledging the skill which has been employed to explain the mysteries.

That a cell of the body other than a cell derived from the organs of generation can take upon itself to live a life independent of the rest of the body, in it but not of it, is hard to believe, and that this should happen from such a cause as an injury or irritation cannot but surprise us still more. But is such an independent existence of a somatic cell incredible? An excitant might have the power to overcome the natural activities of a cell, to enfranchise it from the bondage which all somatic cells owe to their body. We cannot deny the possibility of such a change, though we may feel unable to suggest any method by which it could be brought about. Some, indeed, of the holders of the parasitic theory believe that when the parasite has entered into the cell it lives in the cell and stimulates it to inordinate reproductive activity, that it multiplies within the cell and divides with it, and they consider that this evil influence exerted by the parasite on the cell into which it has entered will suffice to explain the breach of allegiance which certainly takes place. In cancer so marked is this lack of control that many are inclined to hold that it is due to a cutting off of the influence of the nervous system, although such an explanation is rendered very unsatisfactory while we know of innumerable cases in which there has been an absolute loss of control of the nervous system and yet no malignant growth has appeared. That loss of resisting power takes place in some way is clear, while during the last few years evidence has been accumulating that the body can offer successful resistance against cancer. For that cases of cancer may rarely, very rarely indeed, recover spontaneously cannot now be doubted. But while we now know something of the mechanism with which the attacks of the disease-causing germs are repulsed by the opsonins, the phagocytes, and the many other influences which exist for the protection of the body, as yet we know nothing as to the efforts by which the body endeavours to withstand the attacks of malignant disease. But we welcome all evidence that they exist, for with the advance of our knowledge we should be able to strengthen these protective influences and enhance the resistance of the body.

Annotations.

"Ne quid nimis."

THE ELEVENTH REPORT OF THE SLEEPING SICKNESS COMMISSION.

NOT only those who have concern with sleeping sickness, but also those who have the progress and economic development of our Central African possessions at heart, will read with deep interest the recently published Eleventh Report of the Sleeping Sickness Commission[1] which was sent out to Uganda in 1908 under the direction of the Royal Society, and at the suggestion of the late Marquis of Ripon, then Secretary of State for the Colonies, to continue the investigations begun in 1903. This Commission, the third that has been despatched to Africa, had for its leader Colonel Sir David Bruce, C.B., F.R.S., of the Army Medical Staff, the other members being Captain A. E. Hamerton, D.S.O., and Captain H. R. Bateman, R.A.M.C., along with Captain F. P. Mackie, I.M.S. Lady Bruce also accompanied the Commission, and besides rendering other valuable assistance contributed a number of very beautiful coloured and other drawings of the various trypanosomes dealt with in the text of the report. The Commission left England in September, 1908, and the volume now issued deals with its work from that time up to end of July, 1910. Some of the papers included in the report have already been published in the Proceedings of the Royal Society, and upon certain of these we have already commented in the columns

[1] Reports of the Sleeping Sickness Commission of the Royal Society No. xi., London, 1911. Published by H.M. Stationery Office.

of THE LANCET. In an interesting series of "Further Researches on the Development of Trypanosoma Gambiense in Glossina Palpalis" the conclusion is arrived at that in the course of the development of this trypanosome the proboscis of the fly does not become involved, though this occurs with other species such as T. vivax, which also is found in G. palpalis. Experiments proved that after an infective feed the trypanosomes of sleeping sickness disappear from the alimentary canal of the great majority of the glossinæ, but in a small percentage of the flies this initial disappearance is followed by a renewed development in about 28 days, and the tsetse flies in which this renewed or late infectivity occurs can remain infective for at least 96 days, and quite possibly for the remainder of their existence. An invasion of the salivary glands takes place at the same time that the renewed infectivity appears, and it is important to observe that, in the opinion of the Commission, without this invasion of the salivary glands the bites of the flies cannot prove infective. The type of the trypanosomes found in the salivary glands of the glossinæ which become infective is similar to the short, stumpy forms found in the blood of vertebrates. It is believed that this reversion to the blood-type is an essential feature of the infective process. Mechanical transmission of the infection by the fly immediately after an infective feed plays a much smaller part, if any, than has hitherto been supposed. One of the most difficult problems which confronted the Commission was to account for the continuance of the infection in the flies caught on the depopulated shores of the Victoria Nyanza, the whole of the native inhabitants having been removed two or more years previously. It was strongly suspected that some animals were acting as reservoirs of the virus. It was ultimately demonstrated that cattle may in nature carry T. gambiense in their blood, and that certain kinds of antelope are at least potential carriers of the sleeping-sickness parasite, though no evidence was obtained that this occurs in nature. Such animals as the Uganda pig, the crocodile, and Uganda fowls were subjected to experiment, but there was no proof that any of them acted as the host of T. gambiense. Other mammals, birds, and reptiles found on the lake-shore and its vicinity were also examined, and though in the blood of some of them trypanosomes of various sorts were found, there was nothing to show that any of them, excepting a single monkey, harboured the particular parasite of sleeping sickness. The question as to whether there was an ultra-microscopical phase in the development of T. gambiense was also inquired into, but the Commissioners came to the conclusion that it was unlikely that there was any such phase of the trypanosome during the period of its development in the body of the tsetse fly. It was also shown that there could be no hereditary transmission of T. gambiense in G. palpalis. The Commission investigated as far as was possible the diseases of domestic animals in Uganda, and attempts were made to discover the insect carriers of the infection of some of these maladies, and to investigate diseases caused by piroplasms, and also native ailments other than sleeping sickness. In this connexion it is worthy of mention that it was demonstrated that the illness prevalent among the natives in some places, and known locally as "muhinyo," was no other than Mediterranean fever, and that it was spread in Uganda as elsewhere through the agency of infected goat's milk. The distribution of biting flies and ticks, as also the incidence of cattle diseases in Uganda, were mapped out as far as was practicable. This valuable report gives the interesting details of a vast number of experiments carried out at the headquarters of the Commission at Mpumu, about six miles from the Victoria Nyanza. But notwithstanding all that has been done there remain a number of problems in connexion with sleeping sickness still unsolved. With a view of completing the work the Commission has quite recently returned again to Africa. Some changes in its membership have occurred; the places of Captain Bateman and Captain Mackie have been filled by Professor R. Newstead, of the Liverpool School of Tropical Medicine, a recognised authority on medical entomology, and Captain F. Harvey, R.A.M.C. We understand that Lady Bruce once more accompanies the Commission, which is proceeding in the first instance to Nyassaland in order to ascertain if the species of the tsetse fly and the particular trypanosome found there in the recently reported sleeping sickness cases are the same as those which are responsible for causing the disease in Uganda. The question of wild game as possible reservoirs of the virus will also be further investigated.

RECENT RESULTS IN ANTI-PLAGUE INOCULATION.

ALTHOUGH the efficacy of inoculation as a plague preventive is thoroughly recognised and acknowledged by those who have had personal experience, there still exists in some quarters a perhaps not unnatural reluctance to accept this measure as, on the whole, the most effective and essential in presence of an outbreak. It is not superfluous therefore to bring together well-authenticated statistics of the relative incidence of the disease on groups of inoculated and uninoculated persons living under identical conditions. This has been done by Colonel W. B. Bannerman, I.M.S., in his report for 1910 on the working of the Bombay Bacteriological Laboratory, an institution which supplies anti-plague vaccine for the whole of India. During the year the output of this vaccine was 625,690 doses, a substantial increase as compared with 1909, showing that confidence in its use is slowly but steadily increasing. The largest supplies were furnished in the Punjab, Madras, the United Provinces, and the Native States. An important item of evidence as to its prophylactic power is the fact that the whole of the laboratory staff, numbering 116, have remained absolutely immune, though in constant and daily contact with plague-infected rats and fleas. Colonel Bannerman suggests that the unpopularity of inoculation amongst the native classes generally may be due to one, or both, of two verbal misunderstandings: one of these arises from the fact that, in the vernacular, the verb "to inoculate" is translated as "to inject plague" or "to inject plague juice"; the other is the use of the word "sterile" as applied to the prophylactic fluid, meaning, of course, that it contains no living organisms, but understood by the native to imply that its injection will cause sterility or impotence. It is perhaps unfortunate that these terms have become so current in popular phraseology, and the misconceptions as to their meaning on the part of the quite uneducated and ignorant masses of the population are not to be wondered at. Explanation of the real nature of the remedy and of the benefits that may be expected from its use, together with accounts of the success it has already had, that is, education of the people by competent instructors, and in an interesting and attractive manner, as by lectures and lantern demonstrations, should be carried out in all parts of the country. Moreover, this should be done, as Colonel Bannerman states with emphasis, with the cöoperation and hearty support of the chief officers of the civil government, that is, the Collectors of Districts: "The success, or failure, of inoculation in a district depends on personal influence, and the officials of most influence are the Collector and the District Surgeon." We heartily endorse Colonel Bannerman's recommendation. The active personal support of the local governing authority, the senior civil

officer of the district or station, is required. When the British *Raj*, as represented by the Commissioner or Collector, shows that it really wants something done, and intends to have it done, then the leaders of native opinion are likely to get it done. The personal influence and enthusiasm of the civil surgeon are also important factors. Fifteen instances are furnished to prove the efficacy of inoculation, as carried out during the past year. It is stated that they have been selected from many examples received from all parts of India in response to a request for information from the authorities to whom supplies of vaccine had been sent. It would perhaps have been more satisfactory if *all* the statistics could have been collected, instead of a selection; but we imagine that many of them were not sufficiently precise or accurate to be capable of furnishing a trustworthy general induction.

	Population.		Percentage attacks.	
	Inoculated.	Not inoculated.	Inoculated.	Not inoculated.
Dharampur	1,027	2,500	2·30	8·00
Kolhapur	4,118	50,255	0·12	2·25
Sadra	689	600	0·014	4·16
Gujranwala	2,595	19,628	1·58	5·16
Amritsar	5,846	44,243	1·53	5·60
Fyzabad	711	64,371	0·28	1·90
Neemuch	3,350	6,000	1·16	6·36
Do, Skinner's Horse	1,177	9	0·93	100·00
Jaipur	856	131,235	0·23	3·70
Nagpur	3,708	105,587	1·19	7·37
Yeotmal	3,119	7,426	0·86	5·40
Harihar	2,138	1,783	4 30	15·80
Palghat (Malabar)...	10,794	33,383	0·02	0·50
Calicut	2,416	72,565	*Nil.*	0·03
Palni	13,825	3,343	0·64	5·30

A set of examples such as these, collected from a very wide area, and referring, taken altogether, to a considerable number of persons under very different conditions, clearly shows the large measure of protection afforded by inoculation. They also show that there is great variation in the attack rate in different populations—e.g., amongst uninoculated, at Calicut only 0·03 per cent., that is, 22 persons, all of whom died; at Harihar as many as 15·8 per cent., that is, 283 persons, of whom 203 died. Amongst inoculated, 0·02 per cent. at Palghat, that is, 2 persons, of whom 1 died; 4·30 per cent. at Harihar, that is, 92 persons, of whom 18 died. The advantage, however, is always very greatly in favour of the inoculated. The report also records some experiments as to the supposed spread of plague through the medium of wild ducks, which had been suggested as a possible explanation of an outbreak at an oasis in Seistan, 600 miles away from any known plague-infected area. It was found that the rat flea would not take to ducks, either wild or tame, thus disposing of this hypothesis.

METHOD OF INTRODUCING A NEEDLE FOR INTRAVENOUS INJECTION.

INTRAVENOUS injection has now become a common, not to say a fashionable, form of medication, but the operation is sometimes difficult, and the fluid may be injected beside, instead of into, the vein. In the *Journal of the American Medical Association* of July 29th Dr. J. J. Watson has described an ingenious method by which he has seldom failed to enter the vein on the first attempt. If the vein is small or the patient is fat, a ligature is applied above the elbow. A medium-sized sewing-needle is passed through the skin and upper quadrant of the vein and anchors the vein to the skin. The artery forceps or needle-holder used to insert the needle is taken off and clamped on the point side of the needle about a quarter of an inch from the vein. The forceps is gently lifted with the left hand, thus elevating the upper wall of the vein with the skin. With the right hand the injection needle is introduced into the vein almost parallel with its axis. There will be no bleeding if a piece of sterile gauze is pressed over the vein and held there for half a minute as the needle is withdrawn. The three small punctures are covered with collodion. Dr. Watson states that the ease with which this procedure can be executed is surprising. The method may also be used for blood-letting.

RECENT ANTHROPOLOGICAL WORK IN EGYPT AND NUBIA.

WE have from time to time made note of the ever-accumulating volume of literature which is being produced as the result of the labours of various workers in Egypt and Nubia. The Egyptian Government Survey of Nubia has given a great impetus to investigation, for the vast amount of material which it has yielded has furnished a basis for the researches of many specialists, and for many years to come it may well continue to do so. During the season of field work from 1910 to 1911 an interesting portion of the Nile Valley between Dakka and Korosko was examined, and the expedition finished its season's work by excavating Cemetery No. 151, which lay to the south of Wadi Sebua. The fact that 151 cemeteries of all periods have been examined gives some idea of the enormous collection of material, anthropological and archæological, that has been accumulated during the last three years. The human remains obtained in the last season's work have not yet been reported on, for no anthropologist accompanied the expedition in the field; but judging from Mr. C. M. Firth's account [1] of the burials and interred objects an extraordinary interest will be attached to the result of Professor Elliot Smith's examination of the skeletons. One thing that would seem to be apparent from Mr. Firth's report is that as the survey has pushed south along the Nile Valley it has passed beyond the limits of the early and middle Predynastic burials, none of which were met with above Dakka. On the other hand, the early Dynastic period is abundantly represented, and as its burials are traced southwards those indications that were noted in the work of the previous seasons become more clear, and a definite non-Egyptian or local Nubian culture is apparent. This purely Nubian culture in these most southern Dynastic burials manifests itself most clearly in the pottery, which is a finely elaborated development of the simple, yet beautiful, red glazed Predynastic ware. In Egypt proper this full development was never reached, for the use of alabaster obtained such a vogue that the most brilliant evolution of the potter's art was arrested, and only found its full expression among these isolated southern people uninfluenced by the Egyptian fashion for stone ware. It is obvious from this seventh bulletin of the survey that the objects of culture have given a very definite shape to the ideas of the archæologist concerning the peopling of this tract of country, and we may well expect that when the work of the anthropologist is done a very great addition will be made to our knowledge of this early page of the human story. Another recent publication is that of Dr. Marc Armand Ruffer dealing with the representations of pathological types as they are displayed in the wall paintings, carvings, and statuettes of Egyptian workmanship.[2] The fidelity to detail shown by the ancient Egyptian artist

[1] The Archæological Survey of Nubia. Bulletin No. 7. Cairo, 1911.
[2] On Dwarfs and Other Deformed Persons in Ancient Egypt, Bulletin de la Société Archéologique d'Alexandrie, No. 13, 1911.

is well known, and Dr. Ruffer is probably correct in regarding such representations—at any rate, those executed before the advent of Græco-Roman influences—as accurately depicting the distorted proportions of some actual human being. The human desire to indulge in grotesques or a certain inferiority of draughtsmanship on the part of the artist must always be reckoned with, but these elements would seem to be excluded in all the examples chosen to illustrate this work. It is known that the notables of ancient Egypt possessed that curious desire—manifested throughout all history—to have attached to their retinues examples of those human unfortunates who happen to be conspicuously dwarfed or curiously deformed. The dwarf, the hunchback, and the court jester are near relations; the nanus, the pumilus, the morio, and even our own Punch, are all of their family; and what would seem almost more curious than the love of the wealthy to possess them is the willingness of the artist to depict their misshapen forms. Raphael, Titian, Mantegna, Veronese, Valasquez, Carpaccio, and others have lent their art to the portraiture of the dwarf and the hunchback; and some 5000 years ago the artists of ancient Egypt were attracted by the same theme. Dr. Ruffer has classified the dwarfs and deformities represented in the art of these old workers, and has done good service in showing the error of the oft-repeated assertion that these little people were normal members of one of the dwarf tribes of Africa. Achondroplasia, Pott's disease, and talipes are easily diagnosed from many accurate representations dating back at least 4000 years; rickets appears to be manifested in the subjects of some wall drawings, and other malformations, though well depicted, are of somewhat uncertain origin. It is interesting to note that the examination of the actual remains of the people has yielded results that very well accord with the author's conclusions. The Queen of Punt, that mysterious woman whose queer distorted figure has puzzled so many people, still remains a pathological as well as an ethnological riddle, for Dr. Ruffer, though he has determined that she had a daughter of the same type, has not succeeded in diagnosing her condition.

THE TREATMENT OF THE VACCINATION SITE WITH PICRIC ACID SOLUTION.

ANY improvement in the method of treating vaccination scratches and the consequent inflammatory processes will be heartily welcomed by those who have had much experience of vaccination. Although the numbers of untoward results are nowadays comparatively small, the acute inflammatory conditions that sometimes supervene are always annoying and often extremely painful to the patient and worrying to the medical man. In THE LANCET of Nov. 18th (p. 1397) Professor J. F. Schamberg and Dr. J. A. Kolmer, of the Philadelphia Hospital for Contagious Diseases, show that by using a 4 per cent. alcoholic solution of picric acid painted upon the vaccinated area 48 hours after the insertion of the lymph the degree of local inflammatory reaction is lessened, as is also the amount of constitutional disturbance. These observers believe that the improved conditions are the result of the germicidal action of this solution, as they find that the micro-organisms in the skin, or a large proportion of them, are killed off when the solution is applied. There seems, however, to be an additional advantage in the fact that the epithelial cells are hardened or toughened by the action of the picric acid. A kind of natural aseptic dressing is thus formed and kept in perfect condition without any bandaging or constriction of any kind, so that there is no interference with either the lymph- or blood-vascular circulations. Professor Schamberg and Dr. Kolmer are very careful to put this method forward simply as tentative and preliminary, and suggest that others interested in vaccination should repeat their experiments and see whether they obtain equally good results.

A PROTEST AGAINST THE INDISCRIMINATE USE OF THE ORGANIC COMPOUNDS OF SILVER IN OPHTHALMIC PRACTICE.

IN the *Johns Hopkins Hospital Bulletin* for November Professor Samuel Theobald has protested against the indiscriminate use of the organic compounds of silver in ophthalmic practice. Whether as the result of their greater penetrative power or of the freedom with which they are used, protargol and argyrol are responsible, he thinks, for many cases of conjunctival argyria. Before these compounds were introduced argyria was practically never seen except in old cases of trachoma. It has now become a common practice to use the organic compounds of silver in both acute and chronic catarrhal conjunctivitis. This Professor Theobald regards as unnecessary and indefensible, as a collyrium containing half a grain of sulphate of zinc and 10 grains of boric acid to the ounce is cleanly and is more surely and promptly efficacious than the silver compounds.

THE PREVENTION OF BERI-BERI AND MALARIA.

Dr. Max Moszkowski, of Berlin, who undertook an expedition, which lasted eight months, from May, 1910, to January, 1911, to explore the Mamberamo river in Dutch New Guinea, was very successful in preventing both malaria and beri-beri, and gave to the Berlin Medical Society an account of his methods which appears in the *Archiv für Schiffs- und Tropen-Hygiene* for October. The Mamberamo river had, he tells us, a most unenviable reputation. Every previous expedition had been ruined by malaria or beri-beri, so much so that the local steamboat company had forbidden its captains to enter the river at all. Dr. Moszkowski was waiting at Singapore, expecting to join a Dutch military expedition to the river, some hundreds strong, when he got a telegram directing him to go there, but telling him that the expedition had had to be given up on account of a great outbreak of illness. On the day it officially ended there were 42 per cent. on the sick list, and all three Europeans had been attacked by beri-beri, from which several natives died. He had to start quickly, and what preparations should he make? He knew of Braddon's work on cured rice, but cured rice was expensive, and besides it does not keep well. He read Schaumann's long report on phosphorus starvation and beri-beri, and realised that if he fed his men on the rice of commerce, polished rice, they would in about three months develop beri-beri unless he gave the men "polishings" too. But polishings could not be got in the time, and besides the natives do not like them. He knew that Hulshoff Pol, of Buitenzorg, recommended the addition of katjang-idjoe beans (Phaseolus radiatus), but he dared not trust to these alone, as the just-abandoned expedition had been supplied with them, and had yet been decimated by beri-beri. In this difficulty he bethought himself that beri-beri was really a disease of civilisation, not attacking the untutored native who grows, and husks, his rice for himself, but appearing only when coolies are gathered together in numbers on plantations, and get their rice brought to them from mills. He had himself lived on rice in the back country of Sumatra without getting beri-beri, so he decided to take with him paddy, unhusked rice, and carry a rice mortar or two, and have the rice husked daily in the native way. This trebled his baggage and greatly increased the work of the expedition; indeed, it was a method only possible for a small party like his (two Europeans, three Papuans, and five Malays). They had very arduous work; their boats were capsized, they suffered

great privations, yet came through both dry and wet seasons without a single case of beri-beri—a great credit to his forethought and judgment. He tells us that the katjang-idjoe bean has a most unpleasant flavour, and that the natives will always avoid eating it if they can. When he had it for them he issued ½ lb. daily to each man, and himself saw that they ate it. It takes long to cook, so he boiled it for 20 minutes before he put the rice (1½ lb. per man) into the pot with it, boiled the whole down to a sort of porridge, and served this out. Thus treated, the unpleasant flavour disappears, and not only are the rice and bean eaten, but the extractives and salts are not lost, as happens when the beans are boiled and the water thrown away. Even polished rice may be safely used if cooked in this way, we are told. Dr. Moszkowski had a further triumph, for he gave each man 7½ gr. of quinine every fifth and sixth day, and though he says they at times met veritable swarms of anopheles he had hardly a case of malarial infection, and he escaped altogether himself. The history of this expedition is most satisfactory and written with considerable literary skill, and the author is to be congratulated on the success he attained, in spite of all his hardships, in overcoming the two great sanitary dangers of that region, beri-beri and malaria. But in future we are to expect that, thanks to the work of Mr. E. A. Cooper and Dr. Casimir Funk (THE LANCET, Nov. 4th, p. 1266), the leader of an expedition will be able to take all the special substance required to keep beri-beri away from his men in a one-ounce bottle in his pocket. Of such are the triumphs of medicine.

THE FAR EASTERN ASSOCIATION OF TROPICAL MEDICINE.

AS was announced in THE LANCET of May 27th, the second Biennial Congress of this Association will be held at Hong-Kong from Jan. 20th to 27th, 1912, under the presidency of Dr. J. Mitford Atkinson. The papers will be classified so as to give, if possible, a day to each of the following groups: I. Protozoology, Helminthology. II. Cholera, Plague, Leprosy, Tuberculosis. III. Tropical Fevers, including Malaria, Beri-beri, Dysentery. IV. Surgery, Obstetrics, Infantile Diseases. V. Climate, Hygiene, Sanitation. Medical men in the Far East willing to introduce subjects for discussion should communicate at once with the secretary, Dr. Francis Clark, Hong-Kong Papers may be read in English, French, or German, but a brief abstract in English should be sent in. Papers have already been promised by Dr. J. Mitford Atkinson (Hong-Kong), presidential address on the Progress of Tropical Medicine during the Past 25 Years; Dr. J. C. Dalmahoy Allen (Hong-Kong), on Blood Pressure; Major Weston P. Chamberlain (U.S. Army), on Prevention of Beri-beri among Philippine (Native) Scouts by the Use of Under-milled Rice; and Captain E. B. Vedder (U.S. Army) on (1) the Substance in Rice Polishings which Prevents Polyneuritis Gallinarum and Beri-beri; (2) an Experimental Study of the Action of Ipecacuanha on Amœbæ; Dr. C. Noel Davis (Shanghai), Dr. H. Fraser (Kuala Lumpor), and Dr. Victor G. Heiser (Philippine Islands), papers on Beri-beri; Dr. Richard P. Strong (Philippine Islands), on (1) Immunisation against Pneumonic Plague; and (2) the Etiology of Beri-beri; Dr. Lawrence G. Fink (Burma), on Blackwater Fever in Burma; Dr. Paul C. Freer (Philippine Islands), on Results of the Past Two Years' Work on the Study of Tropical Sunlight; Staff-Surgeon Dr. Fürth (Kiautschou) on Neuere Untersuchungen über Flecktyphus; Dr. George A. Finlayson (Straits Settlement), on Malaria as a Factor in the Etiology of Biliary Calculi; Dr. G. Montagu Harston (Hong-Kong), on (1) The Care of Children in the Tropics, and (2) The Care of the Eyesight in the Tropics; Dr. C. Montague Heanley (Hong-Kong), on the Laboratory Diagnosis of Syphilis; Dr. Gregory P. Jordan (Hong-Kong), on Carbon Dioxide Snow, its Use in Private Practice in the Tropics; Dr. K. Justi (Hong-Kong), on the Diagnosis of Malarial Fever in the Absence of the Parasites from the Peripheral Blood; Dr. O. Müller (Hong-Kong) on the Surgical Treatment of Dysentery; Sir Allan Perry, M.D. (Ceylon), on Indian Native Coolie Immigration; Dr. J. M. Swan (Canton), on Some Rare Conditions which have been met with in the Treatment of Vesical Calculi in South China; Dr. Gordon Thompson (Pakhoi), on Surgical Work in South China; Fleet Surgeon Dr. Uthemann (Kiautschou) on, (1) Stadtanlage und Sanitäre Einrichtungen in Tsingtau; (2) Die Notwendigkeit der Quarantänebestimmungen an den Küstenplätzen Ostasiens nach Möglichkeit in Übereinstimmung zu bringen; Dr. G. Duncan Whyte (Swatow) on Tuberculosis in South China; Mr. J. P. A. Wilson (Johore), Professor Cheng Hao (Canton Army Medical School), Major S. P. James, I.M.S., and Dr. J. A. F. de Moraes Palha (Macau) on subjects not yet announced. The Governor, Sir Frederick J. D. Lugard, will open the congress with an address of welcome on Jan. 20th. A social programme is being arranged. The subscription is 10*s.* 6*d.* ($6 Hong-Kong currency).

VALVULAR LESIONS OF THE HEART PRODUCED BY EXTERNAL INJURIES.[1]

IN 1905 Dr. Ranelletti had an opportunity of examining a carpenter whose health had been completely broken in consequence of an accident in which, while he lay on the ground, a wooden door fell on him from a height of about six feet. The door struck him in the præcordial region, the immediate effects being severe retrosternal pain, partial loss of consciousness, and agonising oppression in the chest. Dr. Ranelletti, at his first visit to the patient, about six weeks after the accident, found evidence of insufficiency of the aortic valves, together with incipient hypertrophy of the heart; another examination made four years afterwards showed that the aortic insufficiency had been followed by aortic stenosis. Recognising the great interest of such a condition, not only from the professional point of view but also in connexion with the compensation of injured workmen, he has now collected in book form the clinical and pathological details of 100 recorded cases more or less analogous to the above, the resulting lesions being either immediate rupture of the valves or else the production of some form of endocarditis. The chapters on etiology, diagnosis, pathological anatomy, and medico-legal considerations are well deserving of perusal, though, or because, they suggest a vista of legal procedure.

THE SECOND INTERNATIONAL CONGRESS OF ENTOMOLOGY.

THE intimate connexion between entomology and disease has been realised only of recent years in a scientific manner. Though vaguely presaged by much older philosophy the doctrine of insects as disease-carriers is of yesterday in practical therapeutics. Yet in a brief time much valuable work has been done in tracing the relationship of the mosquito to malaria and yellow fever, of the tsetse fly to trypanosomiasis, of the cattle tick to Texas fever, for example, and it is easy to see that medical successes will not stop at these points. The appointment by Government in 1909 of an Entomological Research Committee to make further investigations into the relation existing between insects and disease in tropical Africa removed from Great Britain the reproach of

[1] Le Lesioni valvolari del Cuore di Origine traumatica. By Dr. A. Ranelletti. Rome: Armando Di Fabro. Pp. 181, with three illustrations. Price 3 lire.

lagging behind in this great field of scientific investigation. Even prior to that the Sleeping Sickness Bureau and the Wellcome Research Laboratory at Khartoum had made great use of the services of the special experts attached thereto, while we may particularly mention the monograph of Mr. F. V. Theobald on Mosquitoes, and the valuable work of Mr. E. E. Austen on "African Blood-sucking Flies." The coöperation of the entomologist with the medical scientist has before it a wide field for investigation. We have recently received from the general secretary of the International Congress of Entomology, Mr. Malcolm Burr, D.Sc., an intimation that the Second International Congress of Entomology will be held at Oxford from August 5th to 10th, 1912, of which further particulars will shortly be announced. The executive committee invites early provisional notice of intention to oin the Congress, that provision for the necessary accommodation may be made, especially in regard to finding lodgings in the town or rooms in one or more of the Colleges (the last for men only) at a moderate charge. Communications and inquiries should be addressed to the General Secretary of the Executive Committee, care of the Entomological Society of London, 11, Chandos-street, Cavendish-square, London, W. The proceedings of the first Congress are nearly ready, and will doubtless provide excellent reading. The subject matter of this Congress must necessarily prove interesting to the medical profession.

THE INCREASE OF NERVOUS INSTABILITY.[1]

THERE can be little doubt that one accompaniment of any rise in the general level of culture and civilisation in a race is an increase in the number of individuals who either suffer from nervous and mental disease or are liable so to suffer. No one who is at all concerned for the welfare of mankind can view such facts with equanimity. Recent statistics would go to show that out of every two to three hundred inhabitants of Germany one is mentally affected, and in other countries also the ratio of insane to healthy seems to be on the increase. The matter is one which concerns not merely the specialist, but also the general practitioner, for the latter has opportunities often denied to the former on coming in contact with neuropathic and psychopathic patients before their disease is fully established; further, from his knowledge of families and familial tendencies he is often in a position to advise and to direct at an early period in a child's life-history. Dr. Zingerle has written an interesting little book in which he pleads reasonably and forcibly for a better understanding on the part of the general practitioner of his opportunities and responsibilities in the matter of prophylaxis. At almost every stage in the individual's life the practitioner, whether he be accoucheur, school physician, army doctor, or factory doctor, may be called on to advise and to treat patients who, if properly handled, can still be retained as useful members of society, and it is eminently desirable he should have a practical knowledge of modern psychiatrical principles of treatment and their application. Dr. Zingerle enters into the homely details of every-day cases, points out the problems that present themselves and the best way of dealing with them, and argues strongly that less would be heard nowadays of the degeneration of the race if more attention were paid to these matters. Both in the chapters on prophylaxis and in those devoted to a consideration of treatment when once mental symptoms are observed, the practitioner will find much that is suggestive and practicable, and he will admire the sound common-sense that pervades the book.

INTERNATIONAL OBSTETRICAL AND GYNÆCOLOGICAL CONGRESS.

THIS Congress will be held at Berlin on Sept. 10th–12th, 1912. A National Organisation Committee for Great Britain and Ireland has been formed for the purposes of the Congress by representatives from the Royal Society of Medicine (Obstetrical and Gynæcological Section), North of England Obstetrical and Gynæcological Society, Edinburgh Obstetrical Society, Glasgow Obstetrical and Gynæcological Society, and the Royal Academy of Medicine of Ireland. The Central Organisation Committee in Berlin has decided to have a formal discussion at the first session of the Congress on Sept. 10th, on "The Surgical Treatment of the Peritoneum." The duties of the National Organisation Committee of Great Britain and Ireland are (1) to nominate delegates to the Congress for the United Kingdom, the number of official delegates being expressly limited by the Central Organisation Committee to three; and (2) to select a "*rapporteur*" (not necessarily one of the three delegates), who will personally open the discussion on the "Surgical Treatment of the Peritoneum" as this country's representative, and give the views held here on the subject. At a meeting of the National Committee, held in London on Nov. 20th last, it was resolved to ask any Fellow or member of any of the above-named societies who are proposing to attend the Congress at Berlin, and who would be willing to serve as delegates, if nominated by the National Committee, to send in their names to one of the secretaries of the National Organisation Committee: Mr. J. H. Targett, 19, Upper Wimpole-street, London, W., or Dr. Walter Tate, 32, Queen Anne-street, London, W., on or before Dec. 11th, 1911.

A MEETING of the Section for the Study of Disease in Children of the Royal Society of Medicine will be held at 11, Chandos-street, W., on Friday, Dec. 15th, at 4.30 P.M., for a discussion on the Treatment of Tuberculous Joint Disease in Children. Mr. A. H. Tubby, in opening, will deal with the Relative Advantages of Operative Measures. Sir Anthony Bowlby will follow with the Results Obtainable without Operation and Dr. Butler Harris will deal with the Rôle of Vaccine Therapy. Fellows of the Society or Members of the Section desirous of taking part in the discussion are requested to communicate with Dr. T. R. Whipham (honorary secretary), 58, Park-street, W.

Sir Thomas Boor Crosby has intimated that he will preside over a meeting at the Mansion House in connexion with the London School of Tropical Medicine on Wednesday, Feb. 28th, 1912. He has also consented to preside at the annual meeting of the British Medical Benevolent Association to be held at the Mansion House on March 13th at 4 P.M. The new Lord Mayor of London has not been long in identifying himself with the medical work of the metropolis.

Sir Henry Butlin asks us to inform the Fellows and Members of the Royal College of Surgeons of England that he is very grateful to them for their kind message of sympathy.

Dr. William Collingridge, who has been medical officer of health of the City of London for the past ten years, has announced to the Corporation his desire to resign this post, as he is no longer physically equal to his duties.

THE Sultan of Turkey has presented to Dr. David Sandler a gold cigarette case with initial set in brilliants and rubies in appreciation of the amicable spirit shown in Dr. Sandler's publications in the English press.

THE CHEMISTRY, PHYSIOLOGY, AND ÆSTHETICS OF A CUP OF TEA.

CAFFEINE TANNATE AS THE CHIEF CONSTITUENT OF TEA INFUSION.

THE view that caffeine exists in an infusion of tea in the form of a definite compound with tannin is sustained by further experiments. In a previous article upon the subject[1] it was shown that when an infusion of tea (which always exhibits an alkaline reaction) was acidified with any acid a flaky buff-coloured precipitate settled out, especially in the cold, which proved to contain chiefly caffeine tannate. Further, the proportion of caffeine to tannin in this precipitate was found to be 1 of the former to 3 of the latter, and the suggestion was that the compound consisted of 1 molecule of caffeine $C_8H_{10}N_4O_2$, with a molecular weight of 194, associated with 1 molecule of quercitannic acid $C_{27}H_{26}O_{15}$ with a molecular weight of 602. In the previous article the formula was wrongly given as $C_{20}H_{20}O_9$. The ratio of caffeine to tannin in such a compound would be 1 : 3·1. The following is an example of the analysis of this precipitate from a good Indian tea :—

Caffeine	20·93 per cent.
Tannin	62·80 ,, ,,
Resinous and oily matters (by difference)...	16·27 ,, ,,
Total	100·00 ,, ,,

The precipitate amounted to 9·84 per cent. of the tea used in the infusion. A further experiment gave the following results :—

Caffeine	20·89 per cent.
Tannin	62·66 ,, ,,
Resinous and oily matters (by difference) ...	16·45 ,, ,,
Total	100·00 ,, ,,

It follows that the precipitate obtained on making an infusion of tea acid consists principally of caffeine and tannin in the ratio approximately of 1 of the former to 3 of the latter. The presumption is that caffeine tannate is the chief body thrown out of solution by the addition of acid.

When, however, this precipitate is removed by filtration and the filtrate is saturated with ammonium sulphate a further separation of buff-coloured flakes takes place. On analysis these flakes show the following composition :—

Caffeine	24·13 per cent.
Tannin	75·80 ,, ,,

$$\frac{\text{Tannin}}{\text{Caffeine}} = 3{\cdot}14$$

The ammonium sulphate precipitate amounted to 4 per cent. of the tea used in the infusion (5 grammes in 400 cubic centimetres of just boiling water allowed to stand five minutes before pouring off). Calculation shows that this particular tea yielded a total of caffeine tannate of 12·26 per cent. Of this total 8·26 was thrown out by mere addition of acid and 4·00 per cent. by subsequent saturation of the filtered acid infusion with ammonium sulphate. There is no point in separating caffeine tannate first by acidifying and next by saturating with ammonium sulphate. The whole can be thrown down at once by adding ammonium sulphate after acidifying the tea infusion with dilute sulphuric acid. When this precipitate is air-dried and sunk in a mixture of 1 of alcohol and 2 of benzene the caffeine tannate is separated from the excess of ammonium sulphate crystals and resins and obtained in a comparatively pure state. The solution of caffeine tannate in benzene-alcohol mixture readily yields its tannin to lead oxide (litharge), the caffeine being set free. To give an example, a certain tea (Indian) yielded a total precipitate by ammonium sulphate amounting to 11·60 per cent. when dissolved in benzene-alcohol mixture and evaporated to dryness and weighed. The following was the process. A definite volume of the alcohol-benzene solution of the caffeine tannate was evaporated over a weighed quantity of lead oxide. The dry residue was then made into a thick paste with water and extracted with chloroform, which was poured off and evaporated in a platinum basin. The residue from the chloroform represents the caffeine contained in the caffeine tannate. The wet lead oxide paste was then dried to constant weight and the increase of weight shown over the original amount of lead oxide weighed out was regarded to be due to tannin. In this way a residue of 11·60 per cent. obtained by evaporating the alcohol-benzene mixture to dryness gave on treatment in the way just described :—

Caffeine	2·80 per cent.
Tannin	8·80 ,, ,,
Total (caffeine tannate) ...	11·60 ,, ,,

With another tea the total caffeine tannate extracted from the ammonium sulphate precipitate by benzene-alcohol mixture was 12·80 per cent., and the constituents found by lead oxide separation were :—

Caffeine	3·20 per cent.
Tannin	9·60 ,, ,,
Total (caffeine tannate) ...	12·80 ,, ,,

These experiments thus appear to establish that, complex as the composition of an infusion of tea may be, it at least yields a definite substance in the shape of caffeine tannate, the composition of which is constantly shown to be one part of caffeine with three parts of tannin.

THE PREPARATION AND COMPOSITION OF CAFFEINE TANNATE.

Caffeine tannate is a very interesting substance apart from its occurrence in tea infusion. It may readily be prepared by mixing aqueous solutions respectively of tannin and caffeine in the cold, when a milky fluid, sometimes with flakes forming according to the strengths of the solutions, is obtained. If a few drops of carbonate of soda solution be added to the mixture a clear pale yellow solution results. If next a slight excess of dilute sulphuric acid be added caffeine tannate separates in flakes which admit of washing to remove free caffeine or tannin as the case may be. These flakes may be dissolved in alcohol-benzene mixture (1 to 2). On evaporating the solution to dryness a crisp crust of caffeine tannate is obtained. If this residue is taken up again in benzene-alcohol and evaporated over a weighed quantity of lead oxide the two constituents are separated. On evaporating the benzene-alcohol and moistening the mass with water to a paste chloroform may be added which will extract the whole of the caffeine ; the lead residue on drying to constant weight will give the amount of tannin as an increased weight on the lead oxide employed. To give an illustration. A benzene-alcohol solution of the precipitate obtained by adding acid to a solution of caffeine and tannin in weak carbonate of soda was evaporated to dryness. The weight was 0·1 gramme. The residue was re-dissolved in benzene-alcohol and the solution so obtained was evaporated to dryness in a platinum basin containing 3·210 grammes of lead oxide (litharge). The dried mass, after moistening, was extracted with chloroform. The residue (caffeine) from the chloroform, clean and white, weighed 0·025 gramme. The lead oxide, after being exhausted with chloroform, was then dried at 120° C. to constant weight. The weight proved to be 3·287 grammes, which represents a gain due to tannin of 3·287 – 3·210, or 0·077 gramme. The 0·100 gramme of caffeine tannate was thus split into 0·025 gramme of caffeine and 0·077 of tannin, figures which account for the whole of the original substance taken, and which give the product 3·08 when the proportion of tannin is divided by the proportion of caffeine. Caffeine tannate is readily soluble in boiling hot water, but as the solution cools it turns milky. It is, however, permanently soluble in water containing a little alcohol. If caffeine tannate be heated with a little water for some time it assumes the form of an oil.

It was next decided to add an excess of caffeine in solution to a known amount of tannin in solution. If tannin selects a definite amount of caffeine to form a compound it is evident that by estimating the remaining free caffeine in the mixed solution the amount that has combined with the tannin can be ascertained. Thus, 0·3 gramme of caffeine in solution was added to 0·3 gramme of tannin in solution, a few drops of carbonate of soda solution were added to make the mixture quite clear, and then dilute sulphuric acid was added in slight excess. Caffeine tannate readily separated in flakes from which a clear fluid could easily be poured off. The clear fluid was then repeatedly extracted with

[1] THE LANCET, Jan. 7th, 1911, p. 46.

chloroform and the chloroform extractions were evaporated. The data and results were as follows:—

Caffeine taken	0·3 gramme.
Tannin ,, ...	0·3 ,,
Calculated caffeine in excess, assuming that 1 of caffeine combines with 3 of tannin ...	0·2 ,,
Caffeine in excess found	0·189 ,,

It is difficult to extract caffeine completely from a bulky aqueous solution, but the result shows an approximation to a combination of 1 of caffeine with 3 of tannin having been formed.

Next the precipitate obtained (caffeine tannate) was split up by lead oxide as previously described:—

Caffeine tannate taken weighed	0·284 gramme.
Tannin found	0·214 ,,
Caffeine ,, ...	0·075 ,,
Total	0·289 ,,

The evidence is here again strong in favour of the existence of a definite compound of caffeine and tannin, consisting of one of the former and three of the latter.

The reverse experiment was next tried—that is, an excess of tannin in solution was added to a known amount of caffeine in solution:—

Tannin taken	0·30 gramme.
Caffeine ,, ...	0·03 ,,
Calculated excess of tannin	= 0·21 ,,

The mixed solutions were saturated with ammonium sulphate and thrown upon a filter. The filtrate was exhausted with ethyl acetate and the extraction evaporated to dryness (we noted before that free tannin is soluble in saturated ammonium sulphate, but that caffeine tannate is insoluble). The ethyl acetate gave 0·205 gramme free tannin against 0·21 calculated. The caffeine tannate formed was again split up by means of lead oxide, and there were obtained 0·10 gramme tannin and 0·03 caffeine, a total of 0·13 gramme caffeine tannate formed against a calculated 0·12 gramme.

CAFFEINE TANNATE PHYSIOLOGICALLY CONSIDERED.

We suggest that these findings are important from a physiological point of view, because it is highly probable that caffeine in a state of stable chemical union with tannin must differ very materially in regard to therapeutic action from the alkaloid in a free or uncombined condition, especially having regard to the fact that tannin serves to some extent as an antidote to most alkaloids since it forms with them insoluble compounds. Similarly tannin when combined with caffeine is a totally different thing from tannin in the free state. The astringent properties of tannin, for example, disappear when it is combined definitely with caffeine. It follows that tannin in combination with caffeine will not tan. A solution of pure caffeine tannate does not act upon gelatin or proteins, so that when tannin is combined with caffeine its incompatibility with these dietetic substances ceases, and its objectionable retarding action upon digestion accordingly must be modified. If these conclusions are correct it becomes of the utmost importance to determine whether in the enormously popular beverage tea, caffeine or tannin exists in the free state or mutually combined.

We have already shown that to a large extent the teas which are regarded as of high quality by the merchant prove to yield infusions containing caffeine and tannin in the ratio of 1 to 3, and the strong inference is that such infusions contain neither free tannin nor caffeine, but neutral caffeine tannate. The merchant's view of quality would thus appear to accord quite happily with physiological considerations. He is guided, of course, chiefly by the flavour of the infusion, as well as by colour and odour and general appearances. Both tannin and caffeine in the free state have characteristic tastes: the former is astringent and sour, the latter is bitter. A slight excess of caffeine in tea infusion is probably less objectionable than an excess of tannin, since the disagreeable qualities of tannin are more marked. An ideal infusion is one which contains both caffeine and tannin in 1 to 3 proportion—i.e., caffeine tannate—neither constituent being in excess. This ideal is occasionally reached, but, generally speaking, most good teas contain caffeine in slight excess. Caffeine tannate, however, does not possess the qualities of its constituents; it has a peculiar flavour which is smooth and bland, not unlike a very delicate or lightly infused tea. It must be carefully borne in mind that in making these deductions we are not considering the chemistry of the leaf, but of its infusion made by pouring 400 c.c. of just boiled water upon 5 grammes of tea and decanting after 5 minutes—a plan suggested by the tea-taster's method of assaying tea.

THE EFFECT OF "STEWING" SOME TEAS.

The desirable equilibrium may be disturbed by vicious treatment even of a good tea. If an Indian tea be boiled long enough or stewed on the hob a point is reached when tannin appears over and above the amount which can combine with the caffeine to form neutral caffeine tannate. Such an infusion presents the objectionable characters of tannin. When this infusion is saturated with ammonium sulphate the caffeine tannate as such is thrown out. If this is filtered off the excess of tannin will be found in the filtrate, from which it can be extracted by ethyl acetate. Thus the five minutes' infusion of an Indian tea showed a total tannin content of 9·24 per cent. and caffeine 3·70 per cent. On infusing the same tea for one hour the tannin amounted to 16·12 per cent. and the caffeine 4·40 per cent. In the five minutes' infusion, therefore, caffeine was in slight excess (0·38 per cent.) of the tannin, but in the one hour's infusion the tannin is in excess of the caffeine by 2·92 per cent. In other words, 4·40 of caffeine if combined as tannate would mean in the combination 13·2 of tannin, when as a matter of fact the total tannin found was 16·12 per cent.

The experience of making wholesome tea seems to have decided upon a limited time for making the infusion. This limit, in fact, appears to us to insist upon the infusion consisting as far as possible of caffeine tannate and upon the exclusion of an important quantity of free tannin or caffeine present. But even a five minutes' infusion of some teas may not approach this standard. Indeed, in view of our work upon the subject we are able to suggest a classification for teas as follows:—

Good teas are those which on a five minutes' infusion yield only caffeine in the form of caffeine tannate to the infusion, neither caffeine nor tannin being in excess; and bad teas are those which yield on infusion for five minutes a tea containing in addition to caffeine tannate either caffeine or tannin, but especially tannin, in excess.

It is obvious from this classification that a good tea may be made a bad tea, but a bad tea cannot be made a good tea, except possibly by very skilful blending. Excessive infusion will spoil a good tea, but a short infusion of a bad tea may be as objectionable as an excessive infusion of a good tea. On physiological grounds, therefore, the buyer of high-quality teas runs less risk of digestive disturbance provided he makes the tea properly.

These points are interesting in connexion with the light types of tea grown in China. The short infusions of these teas commonly contain an excess of caffeine, which probably accounts for their bitterness. They are less rich than Indian teas, a fact which should make the use of Indian teas more economical, but the best types of them never show the presence of free tannin. A five minutes' infusion of a certain China tea showed a total amount of tannin of 4·60 per cent. and caffeine 2·80 per cent. On the basis of the 1 to 3 relationship of caffeine to tannin in caffeine tannate it is evident that in this tea there is an excess of caffeine—viz., 1·27 per cent.—for the amount of caffeine that can combine with 4·60 of tannin is 1·53, making a total of 6·13 per cent. of tannate. As a matter of fact, the amount of caffeine thrown out as tannate when the infusion was saturated with ammonium sulphate was 6·48, which requires 1·62 of caffeine and 4·86 of tannin. In the five minutes' infusion, therefore, there was 1·27 per cent. of caffeine in excess. On infusing the same tea for an hour, however, the tannin then amounted to 7·14 per cent. and the caffeine to 3·20 per cent. Caffeine is still in excess, for the amount combined as tannate is 2·38 per cent., giving a difference of 3·2 − 2·38 = 0·82 per cent. Some China teas, therefore, are incapable of yielding free tannin, and these are invariably high-priced teas.

ANALYSES OF INFUSIONS OF VARIOUS TEAS.

In the following table will be found a series of analyses of infusions made with Indian, Ceylon, and China teas respectively. The percentage results are based upon 5 grammes of tea used in the experiment, to which were

added 400 c.c. of just boiling water, the infusion being poured off after five minutes. The qualities of the teas from the merchant's point of view are indicated by the brokers' prices which are attached. It will be noted that, as a rule, the high-priced teas yield infusions containing a balance of tannin and caffeine, and in general a larger amount of these constituents. The use of a high quality tea is therefore not only salutary but economical also. A very fine example of Indian tea is No. 7. The infusion contained as much as 4 per cent. of caffeine and 9·50 per cent. of tannin. There was only 0·1 per cent. of tannin uncombined with caffeine and 0·90 per cent. of caffeine uncombined with tannin. The price of this tea was 1*s.* 10½*d.* per lb. On the other hand, Indian tea at about half the price—11½*d.*—gave 8·73 per cent. of tannin and 3·20 per cent. of caffeine, and there was 1·53 per cent. of tannin not combined with caffeine, and the liquor was accordingly harsh and astringent, although the time of infusion was only five minutes. The same applies to the Ceylon teas; a tea quoted at 1*s.* 4*d.* per lb. yielded no tannin over and above what is combined as tannate, while one tea quoted at 10½*d.* gave 2·02 tannin in excess. The tea at 1*s.* 4*d.* again yielded 3·60 per cent. of caffeine, while the tea at 10½*d.* gave 2·96. Ceylon teas, as a rule, show a more regularly balanced composition as regards the ratio of tannin to caffeine (3 to 1), a finding which would seem to show that Ceylon teas are all that can be asked for from a physiological point of view.

* Calculated.

When we come to China teas there is again seen to be some relation between price and the percentage of caffeine. A cheap China tea, for example (6½*d.* per lb.), gives 1·92 per cent. of caffeine, while one at 1*s.* 5*d.* per lb. yields 2·80 per cent. China teas, again, rarely yield an excess of tannin, but nearly always an amount of caffeine in excess of tannin, and caffeine appears to occur in China tea with some constituent other than tannin.

BLENDS AND THE BEHAVIOUR OF TEA WITH DIFFERENT WATERS.

So far we have been dealing with individual teas, but we now come to a consideration of blends. The aim of the blender is of course to produce a palatable tea and, more than that, to mix individual teas so that the whole shall be adapted to the peculiar requirements of different public water supplies. In doing this, does he unconsciously produce a mixed tea in which, whatever the drawbacks of the individual teas may be, a balance of caffeine and tannin somewhere near the ratio of 1 to 3 is effected? It is well known to tea experts that a tea which produces a pleasant palatable infusion with London water may easily be uninteresting or even possibly bad when made with, say, a very soft peaty water in Dublin or with the soft-water supplies of Plymouth, Aberdeen, Swansea, and elsewhere. The consumer has the same experience. He will have made up his mind after considerable trial that a certain tea in his judgment is best, at any rate at home. So convinced is he that the tea is a good one that when he happens to travel he will take care to have the same tea with him only to find out that outside his own district at home the tea becomes indifferent. In other words, he has found a tea which associates perfectly with the home supply of water, but which proves to go badly with waters of different quality. Hence the taster will always be careful to select a tea suited to a particular place, and it is invariably his plan to be sure of this by testing the tea with the actual water supplied to the neighbourhood for which the tea is required. It is difficult to see here what guides him in this matter except it be flavour. The probability is that rich teas are more suitable for soft acid waters than for chalky waters. We know, at any rate, that an acid water will tend to neutralise the alkaline salts in tea which keep tannate of caffeine in solution; it would tend to throw caffeine and tannin in the form of tannate out of solution, and so weaken the infusion, whereas chalky water would have the opposite tendency and draw closely upon the available tannin and caffeine which are present in the form of tannate. This is a mere suggestion which may find little support in practice, but so far as we have examined blends deemed to be suitable for certain water the choice appears to be in the direction we have indicated. Thus in a blend intended for consumption in Dublin, where the water is soft and acid from the peat, the total caffeine tannate amounted to 13·20 per cent., the caffeine and tannin being approximately in the 1 to 3 proportion, whereas a tea supplied to districts in Scotland where the water is soft but not acid the total caffeine tannate amounted to 8 per cent., and a tea for Wales, where the water is again soft but not so acid as Dublin water, the caffeine tannate amounted to 10·40 per cent., while the blends supplied for chalky waters showed amounts of caffeine tannate varying from 10·4 to 11·60 per cent.

In all cases it is interesting to observe that the blends showed a near approximation to the ratio of 1 to 3 of caffeine and tannin as in caffeine tannate, and whatever the individual requirements of different districts may be, the taster seems to know when and how a combination of teas will give a satisfactory result. The varying alkalinity of teas may probably be a factor in the case. What exactly lies behind the choice of a tea to suit the requirements of different districts is a theme which is difficult to pursue on merely chemical grounds, for in addition to the varying chemical characteristics of different water supplies, there are colonies of people who collectively like a strong pungent liquor, while there are others who prefer their tea to be light and delicate in character.

The subject is by no means exhausted, but we submit that the foregoing investigation has thrown some new light upon the real character of tea infusion, especially in regard to correlating æsthetic with physiological considerations. We have not concerned ourselves at all with the chemistry of the leaf, but with the chemistry of the cup of tea, and in our inquiry we have been assisted by devising new methods of examination. We hope that other investigators will be induced to approach the subject from this standpoint and append a short description of the analytical methods employed.

METHODS OF ANALYSIS.

The estimation of caffeine tannate.—In all cases the infusion was prepared by taking 5 grammes of tea and pouring upon the leaves just boiling water to 400 c.c. and leaving the infusion to stand five minutes. It was then filtered. For the estimation of caffeine tannate 200 c.c. of infusion was just acidified with dilute sulphuric acid and then saturated with ammonium sulphate and kept cold. The fluid was then filtered and the filtrate kept for the extraction with ethyl acetate of any excess of tannin that might be present, or of caffeine by means of chloroform. [It may be noted that a very rapid method of ascertaining whether tea infusion contains an excess of

tannin consists in saturating the infusion with ammonium sulphate and filtering. The filtrate will contain any tannin present in excess of caffeine tannate which can be extracted by shaking with ethyl acetate separately and evaporating to dryness.] The precipitate in the filter was allowed to dry as much as possible in a current of air. The filter and its contents were then exhausted with a mixture containing 1 part of alcohol and 2 parts of benzene. The extracts were added together and made up to a definite volume (100 c.c.). A known measure of this (25 c.c.) was evaporated upon a weighed amount of lead oxide (approximately 3 grammes), keeping the mixture thoroughly stirred. The dry mass was then made into a paste with water and extracted several times with chloroform. The chloroform, evaporated carefully to dryness, gives the caffeine in the caffeine tannate. The lead residue was then carefully dried at 120° C. and weighed to constant weight. The increase in weight gives the tannin extracted by the lead oxide. Another portion of the benzene-alcohol solution (25 c.c.) is evaporated to dryness to give the total caffeine tannate.

The estimation of total tannin.—We found that good and consistent results were obtained by taking 20 c.c. of the fresh infusion, adding slight excess of bicarbonate of soda and running in N/10 iodine solution until some petroleum ether shaken after each addition with the mixture showed a slight excess of iodine present by the well-known violet colour. The factor for tannin was each c.c. of N/10 iodine used multiplied by 0·0021.

Estimation of the total caffeine.—This was estimated by first slightly acidulating the infusion with dilute sulphuric acid, then boiling with an excess of lead oxide. After half an hour or so a clear pale yellow fluid resulted which filters perfectly, and can then be several times extracted with chloroform, which on evaporation yields caffeine.

PUBLIC HEALTH IN INDIA.

BY the courtesy of the several authorities concerned we have been favoured with copies of the annual official reports on the various departments of public health administration in the Indian Empire; and according to our custom we present our readers with a brief review of the principal topics dealt with. The reports deal with the calendar year 1910, except those referring to hospitals and dispensaries, which refer to the three years 1908–10. To a certain extent such reports must be belated, but their lessons are frequently none the less valuable.

I. SANITARY ADMINISTRATION.

United Provinces of Agra and Oudh.

The vital statistics are, as usual, calculated on the population according to the Census of 1901—viz., 47,691,782, and the ratios, therefore, are probably far from accurate; but no other method is practicable. The birth-rate was 41 and the death-rate 38·67 per 1000, the former being well above the quinquennial average (38·68) and the latter well below it (43·32). The death-rate was, however, higher than in any other province in India except the Central Provinces, and was slightly higher than in 1909. The infantile mortality (227·3) was lower than in any year of the decennium except 1904, when it was the same. This infantile mortality-rate (the death-rate of children under one year, calculated on the births of the year) is a good guide to the general sanitary conditions that exist, and in 1910 special attention was directed to its causes; of these, malaria was found to be the chief, acting both directly on the infant, and indirectly through the mother; after this came insanitary surroundings, ignorance as to feeding, &c., and accidents or diseases connected with parturition. Prophylactic issues of quinine, special attention to sanitation in certain districts, and the distribution of leaflets giving simple instructions as to the feeding and care of infants were the remedial measures adopted.

Cholera was present during the year and visited all the districts, the death-rate reaching 2·15 per 1000.

Plague also increased considerably, causing a mortality of 3·31 per 1000; two districts, Ballia and Azamgarh, were especially affected, and many were entirely free; a scientific inquiry into this special selection of areas has been started by the Plague Research Commission. The fever death-rate, 27·07 per 1000, was less than the quinquennial average (31·02); the highest mortality was in Bulandshahr (35·39) and other districts in the Rohilkhand division; Garhwal (in the hills) with 17·78, and Ballia (18·16) had the lowest figures. Committees have been appointed in the respective divisions to inquire into the reasons for the extreme variation in the incidence of malaria. Meanwhile the use of quinine has been popularised by making use of new agencies for its distribution, and by doubling the commission on its sale. At Naini Tal there again recurred a prevalence of enteric fever. There were 37 cases in all, of which seven were imported; of the remainder, 26 were pupils at St. Joseph's College. The source of infection was definitely traced to the school latrines. In the year preceding there had been a slight outbreak at this school, traced to a carrier employed in the cookhouse. It is now stated that the latrines were situated in close proximity to the kitchen and dining-hall, and that they have been demolished. The authorities must feel much regret that this step was not taken at least a year previously. We note, however, that out of 206 samples of drinking water at this station examined bacteriologically, as many as 84 were reported to be "unsatisfactory." Advances continue to be made in sanitary works throughout the province. It is encouraging to learn that the Benares septic tank and filters are giving good results and that the Fiddian sprinklers are working well. Flushing of drains is now carried out in many of the large cities with excellent effect.

Major J. C. Robertson, the officiating Sanitary Commissioner, refers to the United Provinces Exhibition that was opened at Allahabad in December last. One court was devoted to medical and sanitary science. The exhibits were chosen and arranged so as to be, as far as possible, both interesting and instructive to the general public. The chief prevalent diseases were illustrated by models, diagrams, &c., leaflets were issued, and demonstrations given daily; also sanitary appliances were exhibited. This new departure is likely to be of very great benefit; the mass of the people will much more readily appreciate things seen than things talked about. We look forward to seeing a repetition in other parts of the country.

Punjab.

The statistics relate to the population as recorded at the census of 1901—viz., 20,108,690. The provisional figures of the 1911 census show a decrease of 1·8 per cent. In some districts it is much greater, in Ludhiana amounting to 23 per cent.; in Lyallpur, on the other hand, there has been an increase of 45 per cent. In this district and some others in the neighbourhood the increase has been due to immigration, while in the districts with diminished numbers the decrease has been chiefly due to malaria and plague. The birth-rate is returned as 42·7 per 1000 and the death-rate as 33·28; these figures are satisfactory compared with the quinquennial averages of 41·1 and 45·64. The birth-rate is, indeed, higher than in any other area except the Central Provinces, where it was 55·42. The rise in the birth-rate is a natural sequence of the healthy conditions of 1908–09, and represents the recovery of the people from the malaria and scarcity of the preceding years. The figures are, however, to be corrected by the Census which has taken place during the present year; in certain cases, such as the two just mentioned, this altogether alters the ratios.

The death-rate was 33·28, very much below the quinquennial mean (45·64), this being principally due to an improvement in plague and fever. More than half of this death-rate (17·10) was nevertheless due to fevers, and the plague mortality (6·74) shows a large increase over the two years immediately preceding. Cholera was less prevalent than in the quinquennium, though more so than in 1909; it appeared in the neighbourhood of Simla, but one case only was admitted in Simla itself, and no outbreak resulted. The small-pox death-rate (0·15) was lower than in any year since registration of deaths was introduced. Plague recurred with considerable severity after two years' intermission; it was most prevalent in the Delhi division and in the centre of the Punjab. The principal measures taken to control the disease have been inoculation, evacuation, and rat destruction. As

to the first, Major S. Browning Smith, chief plague officer, reports that it is gradually making headway; evacuation, on the other hand, is unpopular. Rat destruction, in the opinion of the provincial committee, is impracticable on a large scale and should be confined to places where plague persists during the quiescent period; some statistics are given, however, which appear to tell strongly in favour of trapping, but further experience is required. Fever caused a lower death-rate (17·10) than in any year since 1883.

The Delhi suburban drainage-works have made considerable progress, and an extension of the Simla water-supply is in the incubation stage—that is, the estimate of the cost of the scheme prepared in 1904 and approved by Government of India—is "under preparation." Work has been started on the Delhi water-supply extension required for the Durbar.

North-West Frontier.

In this province, with a population (1901) of 1,908,184, the birth-rate was 38·1 and the death-rate 26·9 per 1000. The death-rate is lower than in any other province in India. Colonel W. R. Edwards thinks that probably the deaths are not so accurately recorded as in the other provinces. Cholera broke out in all the districts, Peshawar suffering heavily, where the cool well water, presumably impure, is preferred to the purer, but warm, tap water. The wells were treated with permanganate of potash, which appears to have had a good effect. Colonel Edwards is averse to energetic measures in dealing with cholera, if in opposition to the wishes of the people, when he thinks they are worse than useless; the only thing that can be done is to offer advice and send out cholera pills and stimulating mixtures. With all respect to Colonel Edwards's undoubted experience, we must remark that this is not the policy that commends itself to most sanitarians; the Hardwar fair is a standing example of what may be done by energetic measures when used with discretion. Incineration of refuse is being attempted at Dera Ismail Khan and Peshawar; there are many objections to the method, however carefully carried out. Colonel Edwards's opinion is that the present filth grounds close to the city are a dangerous nuisance, and that the filth should be removed to a distance of about two miles, where land would be available for its useful disposal. This is very sound advice on the general question, and we do not know of any local circumstances at Peshawar to prevent its adoption.

Central Provinces.

The population of these provinces, including Berar, at the Census of 1901, amounted to 11,970,201; the provisional Census figures of the present year show considerable increase. The birth-rate was 55·42 per 1000, being higher than the quinquennial mean (52·33); it was also the highest recorded in the past three decades, and far higher than any other in India, for which as a whole the last five year rate was 38·64 per 1000. The death-rate was 44·88, also an excess over the quinquennial mean of 38·56, and a much higher rate than in any other province. This was accounted for by an infantile mortality rate of 276 per 1000, and by the fact that 56 per cent. of the total deaths occurred in children under 5 years old. Tetanus and capillary bronchitis were responsible for much, but not all of this; training of midwives is already in operation, and the Sanitary Commissioner confesses that "it is impossible to suggest any measures which would check this enormous death-rate in the near future." Fevers have been more prevalent during the year, and a special malaria officer has been appointed to study the conditions that prevail. With regard to plague, which broke out in the previous year, there was some extension of the area affected; the death-rate was 2·42 per 1000. The usual measures were adopted: evacuation, rat destruction, and disinfection. Some remarkable results are given by Captain Morrison, the special plague officer, as to the efficacy of inoculation. Out of 113 persons living in 27 houses in 11 villages 68 were inoculated, of whom none died; 45 were not inoculated, and of these 42 died. During the year separation of the sanitary from the medical department took place. The sanitary report is presented by Captain T. G. N. Stokes, I.M.S.

Burma.

The population of Burma in 1901 was 8,543,753. Calculated on this basis the birth-rate was 36·04 and the death-rate 28·13 per 1000 in 1910, the former being slightly higher and the latter slightly lower than the average. The birth-rate is lower than in any other province except Madras (33·6), but the Burma statistics are admittedly not to be depended on. The infantile mortality (under one year) was 233·24 per 1000 births. The causes of this were investigated at Mandalay, where 60 per cent. of the deaths were found to be from preventable causes, such as tetanus, bronchitis, pneumonia, premature birth, and malnutrition. At Bassein a similar inquiry was made, and 85 per cent. were found to be due to diseases of the alimentary tract, wasting diseases, and marasmus—i.e., improper feeding. At Maymyo the number of deaths at one year was actually 63 out of 104 births—i.e., 594 per 1000; no explanation is afforded. Five other towns had an infantile mortality above 400 per 1000. This terrible waste of life appears to be on the increase year by year, but it must be admitted that the registration of births is defective. The total death-rate was 28·13, the principal causes being fevers (9·37), dysentery and diarrhœal diseases (1·05), and plague (0·91). The fever death-rate was slightly above the average, and was highest in Thyetmyo (19·06). It is pointed out, however, that the heading "fever" merely means the total number of deaths minus a certain number returned under the few remaining headings given in the form. Plague prevailed in nearly all districts throughout Burma, but was not severe, the highest mortality being 0·42 per 1000 in the district of Amherst, Tenasserim. Active measures were taken throughout the province by disinfection, evacuation, inoculation, and rat destruction. Experience showed that evacuation and inoculation were successful. Trapping of rats answered in small, but not in large, towns; rat driving was found to be expensive, and only of use as a temporary expedient; other measures found to be successful were reduction of the rat harbourage and food-supply. Beri-beri has been inquired into during the past year. It prevails amongst the lighthouse keepers and crews of lightships. In 1909 there were 70 cases, in 1910 only 37. From May 1st, 1911, arrangements have been made for the supply of cured rice only, the results of which change will be watched with interest. Observations on the same disease are also being carried out at certain schools in Bassein, which will be reported later.

(To be continued.)

THE next holiday course of the Berlin Dozenten-Vereinigung will be held from March 4th to March 30th, 1912. The prospectus of the course may be obtained gratis on application to Herr Melzer, Ziegelstrasse, 10/11 (Langenbeck Haus), Berlin.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.—The annual festival dinner of the Victoria Park Hospital was held on Nov. 22nd, at the Hotel Métropole, under the chairmanship of Mr. Andrew Motion, who for many years has been a prominent supporter of the hospital. A large company was present, and the evening was a great success. The chairman was supported, among other friends of the institution, by Sir G. W. Truscott, Sir Edward Coates, M.P., Sir Henry Burdett, Sir M. Bhownagree, Mr. C. G. Marsham, the Mayor of Bethnal Green, and by Dr. E. Clifford Beale, Dr. T. Glover Lyon, and other members of the medical and surgical staff. There were also present a large number of representatives of the various working-men's associations which take an active interest in the work of the hospital and collect money for its support. The chairman, in proposing the toast of "The City of London Hospital for Diseases of the Chest," announced that the sum of £3000 which was urgently needed had been subscribed during the evening. He said that the working men of the district were the backbone of the institution, and that their support was one of its principal assets. His appeal for more subscriptions to the hospitals to save them from nationalisation aroused great enthusiasm. The secretary, Mr. G. Watts, then read the list of recent subscriptions, which amounted to more than £3115, and included £890 from working men. Sir Edward Coates proposed the health of the medical staff in an eloquent speech, and Dr. Glover Lyon replied. The chairman's health was proposed in warm terms by Mr. Herbert Robertson.

THE NEW BOTANICAL LABORATORIES OF THE UNIVERSITY OF MANCHESTER.

THE new botanical laboratories of the University of Manchester were opened on Nov. 3rd by Dr. D. H. Scott, Director of the Jodrell Laboratory at Kew, who was a friend and fellow worker of the late Professor Williamson, whose work on fossil plants from the coal measures placed him in the foremost rank of fossil botanists. The bequest of the late Professor Barker for the foundation of a chair of cryptogamic botany, in addition to the steady growth of the botanical department as a whole, made it necessary for the council to provide suitable accommodation for this subject. At a cost of £12,000 a new block has been erected on the University site, with a north frontage for microscopic work. The building has four main floors and two mezzanines and is a square block 40 ft. by 40 ft. There is a special room for palæobotany on the ground floor. On the same floor is a laboratory for 30 junior students connected directly with the large elementary laboratory which accommodates 40 more students. There is on the first floor a research laboratory, with 40 ft. of north light for microscopic work and places for the workers. The second floor is devoted to cryptogamic botany under Professor W. H. Lang, as well as to investigations in connexion with plant diseases. On the third floor is the laboratory for plant physiology. On the top of the building are greenhouses and other arrangements for the study of plant life. This new block is entirely devoted to laboratory accommodation and does not contain any lecture rooms or museum galleries. On the Behrens estate, some little distance from the University, there are experimental grounds and greenhouses for economic botany. Over the main entrance is a Latin inscription which is an extract from the *Benedicite* of the Prayer Book: "O all ye green things of the earth, praise ye the Lord"—a motto suggested by the architect, Mr. Paul Waterhouse.

Dr. Scott in his address at the opening of the laboratories called attention to the fact that during the 60 years that had passed since the foundation of Owens College there had been only two professors of botany, the first being Professor Williamson and the second Professor F. E. Weiss, the present holder of the chair. Dr. Scott spoke of the many-sided character of Professor Williamson—as a medical practitioner, a botanist, a vigorous and successful lecturer both in the class-room and on public platforms, as an aurist, and above all as a great scientific investigator, especially in a domain which he made his own—viz., fossil botany—and thus brought home to scientific people the importance of those fossil remains which showed structure. Dr. Scott said that besides training medical and science students, the department would offer facilities for students from an agricultural college, and no doubt would do its best to throw light on agricultural problems. All the resources of science would be needed to make agriculture remunerative, not to the big farmer alone, but, what was as important, to those who had the actual work to do with their own hands. We are able to present our readers with two views of the new laboratories.

INFANTILE MORTALITY IN ISLINGTON.

Meteorological Conditions.

THE almost unprecedented persistence of fine weather and high temperature during the present Coronation year, that contributed so much to the success of festivities of all kinds and the enjoyment of all classes, has had, as was to be expected, another aspect in the serious increase of infantile mortality in London. Laertes tells us that "the canker galls the infants of the spring," but it is the infants of the summer that die off most quickly. From the last week in June until the middle of September the shade temperature, as recorded in THE LANCET office, reached 70° F. or more on every day but three; temperatures in the "eighties" were very frequently recorded, and five times in July and August the shade maximum exceeded 90°. In the previous year a shade maximum of 70° to 77° was only reached about 20 times from the middle of July to the end of September. The effect of the great elevation of temperature has naturally been seen in a rise of the diarrhœal death-rate in children under two years old during the third quarter of the year; the deaths in London from this cause, which numbered 58, 239, and 342 in the months of July, August, and September, 1910, rose to 276, 2666, and 1369 in the same three months of the present year; these last figures correspond to an (annual) infectious disease death-rate of 1·3, 6·6, and 4·4 per 1000 for these three months severally, the diarrhœal deaths constituting by far the largest proportion of the total deaths from infectious diseases. The boroughs that have been most affected have been Poplar and Bethnal Green, which had infectious disease death-rates of 11·9 and 11·8 respectively in August.

Report of Medical Officer of Health.

Mr. A. E. Harris, whose report for the year 1910 as medical officer of health of Islington we dealt with in our issue of Nov. 18th, p. 1423, has addressed a special report to his health committee on this matter, which we trust will be taken seriously into consideration by the whole council. He points out that actually more than one-fifth of the infants born in the borough within the year have died—viz., 407 out of 1989—the chief causes being diarrhœa, dysentery, and enteritis, generally of the epidemic form. In the sub-districts of Lower Holloway and Barnsbury the infantile mortality rate was as high as 268 and 297 per 1000 respectively. If the breeder of horses, cattle, or sheep were to lose 20 per cent. of his foals, calves, or lambs, a commission of inquiry would be instituted by the Board of Agriculture to examine into the causes of such a disaster, and when these had been found the application of a remedy would be insisted on. With regard to the deaths of infants, advice is tendered by the Local Government Board, but, as Mr. Harris says, no authority insists that it should be taken.

As to the causation, this is pretty generally known. A special inquiry was made as to the feeding of the 201 infants who died under one year. Only 19 were breast-fed; that is, 182, or 90 per cent., were hand-fed, a circumstance which throws a ghastly light on the cause of the mortality. Now, investigations that have been made in several towns—e.g., Derby—show that, speaking generally, from 60 to 80 per cent. of the infants born are breast-fed, so that it is only from 20 to 40 per cent. of the mothers that require to be induced to suckle their children; in Islington Mr. Harris estimates that the proportion is not more than 30 per cent.; these are the people to be got hold of and instructed. He believes that they are mostly in good health and capable of

FIG. 2.

Laboratory for Plant Physiology, third floor, University of Manchester.

nursing their infants; from inquiries made it appeared that of the mothers of the infants that perished, 63 per cent. were in robust health and 14 per cent. moderately strong, so that 77 per cent. might have nursed their infants, if they had wished, unless obliged to go out to work; only 45, however, of the 201 mothers had any occupation away from their own houses.

The excessive infant mortality this year has been in marked contrast with the healthiness of the third quarter of last year, when the rate in Islington was only 67 per 1000 births. This was on account of the very moderate temperature, the comparative freedom from dust, and the absence of flies that marked the summer of 1910. In 1911 the conditions have been very different; the mean temperature was 5·1° and the highest daily temperature 7·9° above the decennial mean; the rainfall was 3·42 inches below the mean, and the registered sunshine 284 hours in excess. This last element, however, in the meteorological conditions Mr. Harris calls "the saving factor of the quarter," as it doubtless destroyed much bacterial life. To complain of unprecedented heat in a report which also contains praise of excessive sunshine is, of course, only an apparent contradiction, for while sunshine has heat for one of its results, it has other effects, and the germicidal quality must be sought in these, not in the heat.

The Remedy Proposed.

The remedy advocated by the medical officer, by which this excessive infant mortality may be checked, is the employment of health visitors; there is now a large body of testimony as to the value of their work from several points of view. Mr. Harris earnestly recommends that at least three should be appointed to deal with infant sickness and to assist in other directions on points of personal hygiene. We regret to learn that the health committee of the borough council has not taken its medical officer's advice, though it was so far impressed by the statistics furnished, and the facts laid before it, as to instruct him to prepare a memorandum on the dangers of artificial infant feeding and on the extreme importance of breast feeding, this memorandum to be forwarded to the mother of every newly born child. This is better than nothing, but we do not consider it as in any way a satisfactory substitute for the first-hand instruction and personal influence of the health officer.

BRITISH MEDICAL ASSOCIATION:

SPECIAL MEETING OF REPRESENTATIVES.

A SPECIAL meeting of the Representative Body of the British Medical Association was held on Thursday, Nov. 23rd, and Friday, Nov. 24th, in London at the Connaught Rooms, to consider the report of the Council on the National Insurance Bill as amended in Committee of the House of Commons, and to discuss the future action of the Association during the last stages of the Bill and thereafter.

The meeting of the Representative Body was not open to the press, and we are much indebted to the executive of the Association for courteous permission to publish the following account of what took place at this important meeting from the pen of one of our editorial staff to whom admission was granted.

The representatives sat from 10 A.M. until 8 P.M. on Thursday, and from 9.30 A.M. until 5 P.M. on Friday, and every point received the closest attention of all present. It was generally recognised that the decisions arrived at during this meeting would have the most far-reaching consequence to the medical profession, and the gravity of the position was obviously plain to an assembly imbued with a sense of the importance of the occasion and conversant with the details of the measure under discussion.

PROCEEDINGS IN COMMITTEE.

Shortly after the disposal of the more formal items on the agenda paper on Thursday morning the meeting resolved itself into committee, and the deputy chairman of representative meetings, Dr. R. C. Buist, was called to the chair in order that the chairman, Dr. E. J. Maclean, might be free to speak and to move official resolutions. Dr. Buist proved himself to be an admirable chairman in circumstances requiring a high degree of tact, discernment, and knowledge.

It was well known beforehand that a number of representatives, particularly those from the northern counties, had been instructed by their divisions to advocate the rejection of the Bill in its present form by the medical profession, and to advise the immediate cessation of all further negotiations by the Council of the Association. This attitude was reflected in many speeches and proposed amendments. But the general sense of the meeting—largely guided by temperate counsels from the leaders of the Association—was against premature and violent action. It was pointed out that everything was to be lost and nothing to be gained by utilising the "strike weapon" at the present moment, whilst the Bill is still under consideration by Parliament, and before the profession has tried its utmost to shape it into a satisfactory form.

Although there was this wide difference of opinion upon the action that should be taken by the Association, it was quite obvious that all the representatives were agreed that the Bill in its present form was entirely unsatisfactory to the medical profession. From the beginning of the meeting discussion centred itself around the difficult question of immediate action: whether the profession should refuse service under the Bill forthwith, or whether the Association should continue its efforts to amend the Bill up to the last moment.

The business on Thursday included the reception of the Council's report to the divisions upon the position of the profession under the amended Bill. The report of the action taken by the Council since the annual representative meeting in July at Birmingham was also considered, and important correspondence with the Chancellor of the Exchequer arising out of this report was read.

CORRESPONDENCE WITH THE CHANCELLOR.

In reply to representations of the Association that the recent increase in size of the Local Insurance Committees, without provision for any corresponding increase in the number of medical members of such committees, was prejudicial to a friendly reception of the National Insurance Bill by the medical profession, the Chancellor stated that under the Bill the Commissioners have full power to nominate a larger number of medical men where circumstances render it expedient. He further stated that in the case of the large committees it was intended to exceed the number which the Bill at present obliged the Commissioners to appoint. The Chancellor considered that the Bill provided for medical representation on the Auxiliary Committees, and stated that the powers given would be used.

The Chancellor promised to amend the Bill in such a way as to facilitate the supply by medical men of medicines and appliances.

It having been represented to the Chancellor that combinations might be made under the Bill whereby medical men might be employed at a lower rate than that locally paid by an Insurance Committee to practitioners on the local panel, the Chancellor considered that the temptation for making such combinations did not exist under the Bill, inasmuch as any saving effected out of the apportioned moneys would be credited to the Insurance Committees and not to such combinations.

To a submission from the Association that provision should be made for compensation to medical practitioners who may be proved to incur loss in the value of their practices through the operation of the Bill the Chancellor made no reply.

Mr. Lloyd George said that he would propose an amendment to secure that in each case at least one Insurance Commissioner for Scotland, Ireland, and Wales should be a medical man, as is provided in the case of the English Commissioners.

In the leading article on the National Insurance Bill in the last issue of THE LANCET it was assumed that the proceedings of the Representative Meeting would be arduous, protracted, and important. This forecast was fully justified. It was based as much upon the direct indications which had reached us of the feelings and intentions of the various sections of the profession as upon our knowledge of the Council's report and of the recommendations which it proposed to lay before the Representative Body. For the greater part of both Thursday and Friday the Representative Meeting remained in committee. The committee stage concluded on Friday at luncheon-time, and the Representative Meeting then resumed and adopted in quick succession various important resolutions which had been passed by the members in committee.

THE RESOLUTIONS ADOPTED.

These resolutions, among other points, reaffirmed the Association's insistence upon the six cardinal principles of

its declared policy being adopted; pressed for the deletion of the Harmsworth amendment; declared that the actuarial estimate of 6s. per head was inadequate; urged that at least one-tenth of the members of Insurance Committees should be medical practitioners, and that there should be corresponding medical representation upon auxiliary committees; pressed for the appointment of medical men as Insurance Commissioners for Scotland, Ireland, and Wales, for the restoration of medical benefits in the case of Ireland under the same conditions as in England, and for adequate provision for institutional treatment for insured persons. The Representative Body also approved the action of the Council in asserting the right of medical practitioners to provide drugs and medical appliances to insured persons, but not at an inclusive fee.

The declaration of insistence upon the six cardinal points, proposed by the Council and approved and extended by the meeting, must be quoted in full:—

That the Representative Body declare the determination of the Association to insist upon the arrangements made with medical practitioners for giving attendance and treatment to insured persons being consistent with the six cardinal principles formulated and approved by the Representative Meeting of June 1st, 1911, and confirmed by the Representative Meeting, Birmingham, in July, 1911; and that a copy of this resolution be sent forthwith to the Chancellor of the Exchequer and the press, and to each Member of Parliament, through both the head office and the honorary secretaries of divisions; and that steps be taken to ensure that the Chancellor of the Exchequer be informed of the declaration in the House of Commons itself.

It was unanimously agreed on Thursday that this recommendation of the Council (as amended) should be placed first amongst the resolutions passed by the Representative Body.

The final "Declaration with Regard to Future Action as to the Cardinal Principles" must also be quoted in full:—

That in the event of the Insurance Bill becoming law the British Medical Association use every possible means to ensure that no medical practitioner undertake the medical attendance and treatment of insured persons under arrangements that are not absolutely in accordance with the six cardinal principles of the policy of the Association.

In support of this latter momentous resolution the Chairman of Representatives, Dr. Maclean, made an impressive speech, which amounted to a defence of the council's action and an appeal for fair play. He urged the Association to trust in its own strength and in its leaders, and he denied indignantly that there had been any compromise between the Council and the Government. He suggested that it would be disastrous for the profession at the present stage to wash its hands of the Bill and cease to press for amendments. In his belief the resolution was intended to focus the strong determination of the Association to realise its fixed policy, whether by means of present representations made to the Government or in the future by standing out in part or in whole from working under the Bill. The Chairman of Council, Dr. J. A. Macdonald, followed with a short and vigorous justification of the action taken by the leaders of the Association. He deprecated the suspicions which had lately been manifested in various quarters, and he put it to the meeting that in the difficult and unprecedented circumstances arising under the Bill he and his colleagues had not been taken unawares. More than a year ago they had gone into the question of State insurance. They had done all that could be done, and would yet achieve success, provided that they had behind them the loyal and undivided support of the Association. Again, later in the proceedings Dr. Maclean dealt with the rumours and suspicions and hints of disaffection which had been ventilated by certain representatives. His indictment of these signs of discontent made a deep impression upon the meeting, and his final appeal for confidence in himself and in those who were working with him was received with great enthusiasm. The final resolution carried by the representative body was:—

That preliminary consideration should be given to the organisation of the profession for the purpose of protecting their interests under the Insurance Bill, and that in order to prevent sectional defeats of the profession through terms having to be arranged locally between Local Insurance Committees and the profession, the Association take such steps as to secure: (*a*) That the Local Medical Committees throughout the country be kept in touch with one another through the central office of the Association; and (*b*) that no arrangements for attendance on insured persons be completed anywhere until the Association is assured by reports from the Local Medical Committees that terms in conformity with the policy of the Association *in detail* have been agreed upon everywhere.

Before the meeting closed its arduous and responsible task warm appreciation was expressed to the executive officers of the Association, including the editor of the *British Medical Journal*, for all their devoted work, and the concluding vote of thanks to Dr. Maclean was carried with loud acclamations.

THE NATIONAL INSURANCE BILL.

THE MEDICAL PROFESSION IN EDINBURGH AND THE INSURANCE BILL.

DURING the past week the profession in Edinburgh has been largely absorbed in the questions arising out of the Insurance Bill, which has passed through Committee of the House of Commons without having been altered as the profession had demanded. On Tuesday, Nov. 21st, the Edinburgh and Leith Division of the British Medical Association held a large meeting under the chairmanship of Dr. JAMES RITCHIE, and the meeting was unanimous in reasserting the six original cardinal points, while it further expressed unanimously disappointment at the tone of the report on the Bill of the Council of the Association as it at present stood. The correctness of this second opinion has been shown by the action of the Representative Meeting in London passing the newly-worded and strong resolutions on Friday last (Nov. 24th) after long debate.

On Wednesday, Nov. 22nd, a meeting of the Edinburgh and Leith Medical Practitioners' Association was held in the hall of the Royal College of Surgeons. The chair was occupied by Dr. ALEXANDER JAMES, and there was a very large gathering of the local profession.

The secretary, Dr. JOHN M. BOWIE, read a letter from Mr. G. A. Berry, President of the Royal College of Surgeons, in which he said: "My feeling is that the whole profession is bound to make the most determined effort to resist a scheme of legislation which, however beneficent in theory, seems calculated to degrade it, and therefore react unfavourably on the public. It was bad enough to introduce a measure affecting our profession as it would do, without adequate consideration of the conditions under which it could be carried into effect. Now that definite representations have been submitted practically unanimously by the profession, it is little short of an insult to the profession as well as to the public."

Dr. JAMES said they met at a time when they recognised that the real relationship of their profession to humanity was being endangered, and when all they regarded highest, as disciples of the healing art, was being threatened. Why was it, he asked, that this Bill, which promised such beneficial results to a large number of their fellow men and gained for itself the approbation and support of so large a public—why was it received by the medical profession in a spirit of aloofness, rapidly widening into open hostility? The answer was simply because, whilst the general public believed that this Bill would be able to perform all that it promised, the medical practitioner recognised that it was promising what it would not carry out. He felt that it would be unfair to themselves and to the community as a whole if he did not advance the claims of the medical practitioner to special fitness in estimating the value of this Bill in other aspects as well as those which were purely medical. In his daily intercourse with feebleness, suffering, and disease, the practitioner had every opportunity placed before him of interpreting the onset of bodily ills in the light of the social ills of humanity as a whole, and no one better than he could value the influence which successive Acts of municipal and State legislation had been exercising on those social ills. But no one knew better than he that there were limits to this State interference, and practically all of them there that night had years enough and experience enough to enable them to form a judgment as to the real value of the philanthropic and socialistic legislation which the last two or three decades had brought forth, and of which this Insurance Bill was to be regarded merely as the latest instalment. Recognising that, as all political economists had pointed out, the majority in any community must always be formed of the inferior, the practitioner in medicine could discern that the more readily such legislation commended itself to the majority, then with the least ultimate benefit from it accruing to the community, there would be the greatest immediate benefit accruing from it to the philanthropic legislators themselves. Philanthropic legislation was far too often the worst kind of legislation, because it tended to bring out the worst, both in those who made the law and in those who had to obey it.

Dr. JAMES SMITH, a well-known worker in the east side of the city and a member of the School Board, who said that he

was of the same shade of politics as Mr. Lloyd George, submitted the following resolution :—

That this meeting resolves that no medical practitioner ought to accept office under the National Insurance Bill if passed into law in its present form.

Professor F. M. CAIRD heartily supported the motion and the position the profession were taking up.

Dr. ROBERT ROBERTSON, who is a member of Edinburgh town council, moved the second resolution :—

That a pledge be given by each medical practitioner in the Edinburgh area that he will not accept office under the Bill if it becomes law in its present form.

This was seconded by Dr. A. LOGAN TURNER, who further proposed that a message should be sent to Lancashire and Cheshire : "United, we stand with you."

Dr. E. F. ARMOUR moved the third resolution :—

That each medical practitioner in the Edinburgh area binds himself not to accept any kind of appointment under the Insurance Act, unless the terms of such appointment have been approved by a local representative medical committee.

This motion was warmly supported by Dr. G. A. GIBSON, who said they were going to boycott the Act and all its doings. If the Bill became an Act in its present form it meant that the profession would be reduced to little better than the level of Poor-law inspectors, and the medical work of the past would become null and void.

Dr. W. ALLAN JAMIESON, Vice-President of the Royal College of Physicians, and others addressed the meeting. It was determined to send a copy of the resolutions to the Chancellor of the Exchequer and others. Dr. W. Craig, of Fife, who was on his way to London to attend the Representative Meeting, was asked to convey the resolutions to that body. All the propositions were carried with acclamation and the meeting was one of the most enthusiastic which has been held.

IMPORTANT MEETING IN GLASGOW.

Defending Rights and Privileges.

A meeting of the Fellows and Licentiates of the Royal Faculty of Physicians and Surgeons and of members of the medical profession in the city and district was held in the Faculty Hall, St. Vincent-street, Glasgow, on Saturday, Nov. 25th, for the purpose of considering a report by the Council of Faculty on the National Insurance Bill. Dr. JAMES A. ADAMS, President of the Royal Faculty, occupied the chair, and there were above 200 medical men present.

The CHAIRMAN said that the Insurance Bill had been so juggled with and changed that they really did not know where they were, and they had a dread that they might be jockeyed into a position which would be difficult to get out of. The Council had therefore determined to formulate certain resolutions which he would submit to the meeting. The first resolution which he moved, in the name of the Council, was as follows :—

That the Insurance Committee should include a representation of duly qualified medical practitioners to the extent of one-eighth of the total number and adequate representation on the auxiliary committees.

Dr. JOHN BARLOW, in seconding, said that many of the points to which medical men attached importance were left for final decision to the Insurance Committees. These would be formed in each county or burgh in Scotland. He was in favour of the Bill though opposed to contract practice altogether, but he thought they were all in agreement that a proportion of three medical practitioners out of 48 or 80 members, as the case might be, was not adequate. The proportion suggested by the resolution would ensure the medical point of view being brought forward fairly.

Dr. J. MCGREGOR ROBERTSON and Dr. J. HAMILTON suggested the desirability of discussing the question of approval or non-approval of the principle of the measure before dealing with details. Dr. Robertson thought that the members should be asked to say "whether they approved of chaining round the neck of the profession for ever the abominable system of contract practice."

The CHAIRMAN desired the public to recognise that while they made this protest they were doing all in their power in a courteous and tolerant manner to consider the scheme and to do the best they could with a bad bargain. Registering pious opinions would not stop the Bill from passing. He thought they should deal with the resolutions before them first.

The resolution was then approved.

The CHAIRMAN then moved the second resolution as follows :—

Wherever a voluntary hospital or other charitable institution is used by the Insurance Committee, adequate payment for the maintenance and treatment of the patient shall be made to such voluntary hospital or charitable institution by the Insurance Committee.

Professor J. GLAISTER, in seconding, reminded them that contributions of workmen and their employers in Glasgow formed practically two-thirds of the whole revenue of the hospitals, and were it not for the bequests from which deficiences in annual expenditure were made up the hospitals in Glasgow would be bankrupt. If the workmen's and employers' contributions were withdrawn, as they probably would be on the passage of the Bill, the hospitals would lose their power to afford charitable relief to those who required it. He thought, however, that at present they should continue the voluntary organisations as long as possible, and he strongly supported the resolution on the ground that if people were to be taxed for the funds under the Bill, when they required hospital treatment they should pay the corresponding proportion of the cost which they laid upon the hospital fund, and that fund should come from the local Insurance Committee.

Dr. MCNICOL moved a direct negative, and the amendment was carried.

The third resolution, moved by the CHAIRMAN and amended by Dr. HAMILTON, was as follows :—

That this meeting is of opinion that the other recommendations contained in the six cardinal points of the British Medical Association not included in the preceding resolution should be incorporated in the Bill.

This was carried.

Dr. ROBERTSON said that before that resolution was approved he would submit the following motion :—

That while this meeting approves of the amendments in details submitted on behalf of the profession by the British Medical Association, if the Bill is forced through more or less in its present form, it does not approve of the method of dealing with the profession which is at the foundation of the medical provisions of the Bill.

The Bill, he said, was contract practice writ large, with, besides, the stamp of the Government, of Parliament upon it, and while at any moment the medical profession, in any body or as individuals, could destroy, if they chose, medical contract practice as it existed, if they permitted this Bill to pass they would never destroy it, but would be riveting it round the neck of the profession for ever.

The resolution was carried.

On the motion of Dr. PERRY, seconded by Dr. DUNCAN, the meeting agreed unanimously to the following resolution :—

That in the event of the Insurance Bill becoming law without the amendments recommended by the British Medical Association, this meeting shall endeavour to ensure that no medical practitioner shall submit to the rules under the Bill.

A resolution was also carried as follows :—

That the foregoing resolutions be forwarded to the General Medical Council, the Prime Minister, the Chancellor of the Exchequer, and the Members of Parliament for the city of Glasgow.

ABERDEEN AND DUNDEE: THE MEDICAL QUESTIONS OF THE NATIONAL INSURANCE BILL.

The clerk and treasurer of the Aberdeen Royal Infirmary has sent a letter in the following terms to the local Members of Parliament :—

National Insurance Bill.

I am requested by the directors of Aberdeen Royal Infirmary to communicate to you the following resolution which was unanimously passed, (1) on 2nd instant, by the council of the British Hospitals Association; and (2nd) on 10th instant, by a large and representative meeting of hospital managers and administrators held in Glasgow, viz. :—

"That the National Insurance Bill is incomplete unless it provides for the hospital treatment which insured persons must have if their medical needs are to be covered by the Bill."

The directors fully concur in the resolution. They are of opinion that in omitting provision of hospital treatment for insured persons the Government has failed to realise the serious position in which such persons will be placed. It is certain that many of them will require medical and surgical treatment which cannot be rendered to the best advantage otherwise than in hospital, and yet the fact that they will be statutorily provided with sick and medical benefit, will in itself—under the constitutions of most of the voluntary hospitals—disentitle them to receive free treatment and maintenance in those institutions. In these circumstances the directors trust that you, along with your fellow Members of Parliament, will give this matter most serious consideration, with the view of, even yet, having this grave defect in the Bill rectified. I am further desired to say that the directors regard with great apprehension the possible effects of the Bill, if passed in its present form, upon the financial interests of the hospital.

The directors of the Dundee Royal Infirmary have forwarded a copy of the same resolution to the Members of Parliament for Dundee, Montrose Burghs, East Perthshire, East Fifeshire, and St. Andrews Burghs. To this the following communication has been appended:—

The directors (of the Dundee Royal Infirmary) are of opinion that the passing of the Bill in its present form will have such an effect upon the finances of this hospital that its work among the sick and hurt poor of the city will be greatly crippled. Over a fifth of the whole income of the institution is derived from contributions from the employees in mills, factories, and workshops, who will be insured persons under the Act, and from the personal knowledge of the directors they are satisfied that these contributions, as well as those of employers, will, if not altogether, at least to a large extent, be withdrawn upon the passing of the Act. The necessity for being able to give effective hospital treatment in a city such as Dundee is evident, when it is taken into account that the accommodation in the houses of large numbers of the population does not admit of their being properly attended to at home when serious illness overtakes them. If, therefore, the infirmary be not as available as in the past the workers would be the first to suffer. With regard to the maternity benefit, the directors would point out that the Dundee Royal Infirmary includes the Dundee Maternity Hospital, in which 370 indoor and 890 outdoor patients were attended last year. If it be decided that the indoor patients in a hospital are to receive the maternity grants for the upkeep of their homes during the four weeks of their inability to work it would seem reasonable that some arrangement should be made by which an allowance might be given to the hospital during their residence therein. The directors trust that you will give favourable consideration to any amendments which may be proposed for the provision of hospital treatment when required by insured persons, and that you will join in supporting such amendments.

A meeting of the medical practitioners in the area of the Aberdeen Division of the British Medical Association was held on Nov. 22nd. There were over 100 medical men present, and after a full discussion all the recommendations of the Council of the Association were unanimously and enthusiastically adopted, and the following resolution passed:—

That this meeting resolves that unless the Bill be so amended as to satisfy the medical profession in reference to the six cardinal points the profession refuse to work under the Bill.

At a meeting of the Dundee Branch of the British Medical Association the following resolution was passed:—

That the branch express its dissatisfaction with the National Insurance Bill as it now stands, and declare its determination not to undertake service under the Bill unless our cardinal points are granted.

Both the Aberdeen and the Dundee resolution were forwarded to be read at the meeting of Representatives of the British Medical Association in London.

THE QUESTION OF MEDICAL BENEFITS IN IRELAND: AN APPEAL TO MR. REDMOND.

In a letter addressed to Mr. Redmond by Mr. J. Smith Whitaker on behalf of the British Medical Association and the Irish Medical Association sets out the opinions of the Irish medical practitioners as to the provision of medical benefits under the Insurance Bill in Ireland. It is argued that if the Bill applies to Ireland at all the medical benefits given should be on the same terms as in Great Britain, though adjustment may be necessary to meet the case of the Irish Dispensary Medical Service. The Irish medical profession, it is stated, now withdraws any demand for a rate of remuneration to be fixed in the Bill, and will accept the view "that the terms of remuneration must depend entirely on the amount and nature of the work and other conditions of service." The well-reasoned letter considers the attitude of the Chancellor of the Exchequer, in having excluded Ireland from medical benefits, to be due to political expediency, and urges Mr. Redmond to remember the grave defects in the existing Irish Dispensary Service.

THE CONJOINT VIEW OF THE BRITISH AND IRISH MEDICAL ASSOCIATIONS.

At a meeting of the Conjoint Committee of the British and Irish Medical Associations, held last week, the following resolutions were passed:—

This Conjoint Committee approves of the restoration of medical benefit for Ireland, and on behalf of the profession in Ireland are prepared to accept the Bill under the same conditions as in Great Britain. We protest against the compulsory imposition of any duties under the Act on the Poor-law medical officers. It should be the object of wise statesmanship to emancipate the industrial classes from the Poor-law with the degrading effects on their moral and self-respect that come from charitable relief. Medical benefits administered on the conditions we desire would go far to accomplish this.

We strongly deprecate any suggestions that it is the duty of the profession, either as a whole or by any section of its members, to draft the scheme by which medical benefit may be applied to Ireland. The Irish professions are not more unreasonable than their English brethren, and we are convinced that if the same terms are offered in Ireland as in England they will be accepted. As Irishmen we protest against any attempt to treat Irish doctors with less justice and fairness than English doctors are treated under the Bill; we also protest, and if possible more strongly, against the imputation that in making our demands we are actuated by greed, rapacity, or a desire to wreck the Insurance Bill. This committee offers to afford any assistance in its power in consultation with any Members of Parliament or others who in an official capacity are concerned in formulating proposals for the restoration of medical benefits to the Bill.

THE FEELING IN NORTHERN IRELAND.

At a meeting in Londonderry on Nov. 22nd of the medical practitioners of the North-West of Ireland, the following resolution was unanimously passed:—

That we, the doctors of Londonderry and Donegal, are of opinion that the medical benefits under the Insurance Bill should be extended to Ireland on the same terms as may be acceptable to the profession in England.

The Belfast Trades Council has issued a circular, which has been forwarded to local trades unions, Irish trades councils, and public health authorities, strongly protesting against the exclusion of medical benefits from Ireland. A deputation, it is said in this document, representing 60,000 trade unionists, waited on Mr. Lloyd George at the House of Commons, and protested against the exclusion of Ireland from medical benefits, and the trades councils of Dublin, Limerick, and Belfast have constantly been urging the retention of Ireland under the full scheme. "The proposed exclusion," the circular says, "is to be made in favour of the Irish dispensary system, which, as you are aware, is controlled by medical men who have gained their experience in workhouses, and are appointed by boards of guardians, who are usually influenced in their selection by reasons entirely unconnected with the humane character or ability of the candidates. If this system, condemned by all recent investigation, is not good enough for England, Scotland, or Wales, why should the Irish party or Mr. Lloyd George consider it good enough for Ireland? We believe the dispensary system tends to perpetuate pauperism and degrades the Irish people." In this document it is also urgently pressed that unemployment insurance should apply to Ireland, with all fair and necessary modifications to suit the agricultural portion of the people. It is also suggested to hold public meetings and press Parliament on these lines.

It is clear now that the profession in Ireland wish for the inclusion of medical benefits on the same conditions as in England, for they see that unless this is done the alternative is club practice of the worst kind, but whether this will be allowed seems to depend on which politician has his way among the Nationalist Members. The abuse of the hard-worked dispensary medical officers should not have been published.

THE NATIONAL INSURANCE BILL AND THE HOSPITALS OF LONDON.

At a meeting of the Central Hospital Council for London, held at St. Thomas's Hospital on Nov. 23rd, the effect upon the voluntary hospitals of the passing of the National Insurance Bill as it stands at present was considered, and it was unanimously agreed—

1. That the effect upon the voluntary hospitals must be to diminish their income very seriously, and consequently to lessen the number of beds they will be able to maintain, as well as gravely to impair their efficiency as curative institutions, schools of medicine, and training schools for nurses.

2. That the National Insurance Bill will be incomplete until it provides for the hospital treatment which insured persons must have if their medical needs are to be covered at all adequately by the Bill.

THE POSITION OF CERTIFICATED DISPENSERS.

An important deputation representing the Society of Apothecaries and the Association of Certificated Dispensers waited upon the Attorney-General in his private room at the House of Commons on Thursday, Nov. 23rd, in order to urge the adoption of certain amendments to the Bill for the purpose of protecting the interests of persons holding the certificate in dispensing. The deputation received the most satisfactory assurances from Sir Rufus Isaacs that the Government had no intention of allowing the provisions of the Bill to prejudice the interests of the society's dispensers, and while agreeing that Clause 14 as at present amended in committee was unsatisfactory in this respect, undertook that the measure should be so further amended that these rights were fully protected.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH FOR 1910.

Rhondda Urban District.[1]—In the Rhondda Valley there is progress, though it be but slow progress. It is a large district composed of narrow valleys, where there have been much overcrowding, a high death-rate, and other unsatisfactory conditions. But, nevertheless, the death-rate is not so high as it used to be, and more houses have come into existence, though this is not a locality likely to tempt the builder. Numerous bench-marks taken throughout the area show that during the last 12 years the whole district has sunk. In many localities this subsidence amounts to 5 feet and more, the maximum being 7·95 feet at Llwynypia. This naturally endangers the stability of buildings and may cause the breaking asunder of water-mains, sewers, and pipes of different sorts. While the rapid development of the mining industry, in which 69 per cent. of the males above 10 years of age are engaged, helps to produce this subsidence of the soil, it has attracted a large working-class population, all needing dwelling-houses. Thus we are told that in 1871 there were only 3872 houses, there are now 26,000 houses. They are nearly all small cottages, with three bedrooms, a kitchen, and a parlour. At the Census of 1901 the average population was 5·92 per house, and the hope is now entertained that this average has fallen to about 5·8; this, if not much of an improvement, is a change in the right direction. The reduction in the death-rate is far more satisfactory, as the average for the ten years 1890–99 was 21·1; for the years 1900–09 only 18·4, and for the year 1910 we have a still further decrease to 15·7 per 1000 of the population. The infantile mortality is 56 per 1000 less than the average of the last 20 years, but it still amounts to 136 per 1000. This is the figure for 1910, while that for the 77 great towns was 115, and for England and Wales 106 per 1000. Thus the state of affairs in the Rhondda valley is still very unsatisfactory. The report expresses great satisfaction with the services rendered in checking infantile mortality by the two lady inspectors, who teach mothers how to wash and feed infants, while informing the authorities if there is anything insanitary in or about the dwellings. The difficulty of disposing of household refuse adds to any unwholesome conditions. There is but one destructor, which cannot consume more than 16 tons of refuse per day, and this at the rather elevated cost of 1*s.* 9*d.* per ton. But there are 200 cartloads of refuse collected daily, and therefore most of this is thrown down the 11 refuse tips scattered throughout the urban district. There it rots and ferments and creates unwholesome conditions which are likely to cause trouble in the future. Power for a scheme, however, has been sought to deal with this important matter. Dr. J. D. Jenkins has undoubtedly a busy task in watching over so scattered a district, where there are several exceptionally difficult problems to solve.

Glamorgan County.—Dr. David J. Morgan only came into office in April, 1910, so that the present report is based to a large extent on the work of his predecessor, Dr. W. Williams. The administrative county consists of 19 urban and eight rural districts, with a population of over 700,000 and a death-rate of 13·97 per 1000. The infantile mortality was equal to 125 per 1000 births registered. The highest was 151 at Aberdare, and the lowest 64 at Penarth. The overcrowding in the industrial districts is considered one of the principal causes of this evil, and the sanitary and educational authorities alone cannot accomplish all that is necessary. A separate chapter is devoted to each of the urban and rural districts into which the county is divided, and it would require much time and space to deal with them all. On reading over the various complaints made and the enumeration of the many requirements that have to be satisfied before the sanitary conditions can be considered perfect, it seems quite evident that these places are too small to carry out all the public works they need. There are the disposal of sewage and the prevention of the pollution of rivers; then come the house refuse problem and the slaughter-house difficulty. Obviously many of these districts should unite and share the cost of one central establishment between them. It is to be noticed that in most places complaints are made about the slaughter-houses, and where no complaint is made we get a statement that is sometimes even more condemnatory. Thus for Neath borough, and though it has a population estimated at 17,000, we are just simply told that the slaughter-house "was visited weekly by the sanitary inspector." When we consider that no killing should be allowed except in the presence of a veterinary surgeon, what are we to say about this one visit a week, and that only by a sanitary inspector. With the aid of tramways small urban and rural districts can be brought into cheap, prompt, and easy communication one with another. Therefore one large public abattoir, with a proper staff of veterinary surgeons attached, might supply the needs of a very wide area. By thus uniting different districts there would be less difficulty in obtaining the necessary funds. Penarth, which has the record for a low infantile death-rate, has also a very low general death-rate—namely, 9·08 per 1000. The zymotic death-rate was only 0·49 per 1000, and there was no summer diarrhœa. The water-supply is described as soft, pure, constant. The sewers have large flushing tanks, and are stated to be in a good condition. The outfall is taken as far as low tide, and house refuse is removed at least three times a week. There are five private slaughter-houses; these are clean and constantly inspected. Still the medical officer of health urges that under such conditions the meat-supply cannot be properly controlled, and that the private slaughter-houses should be replaced by a public abattoir. In spite of this criticism, it will be seen that the sanitary conditions at Penarth are improving.

Criccieth Urban District.—The annual report of Dr. E. Lloyd Owen, medical officer of health for the Southern Division of the Carnarvonshire Combined Sanitary Districts, for the year ended Dec. 31st, 1910, is divided into three parts. Part 1 deals with the administration of the Factory and Workshops Act, 1901. Part 2 consists of four tables of statistics, viz.—Table I., Vital Statistics of the District for 1910 and the previous ten years; Table III., Cases of Infectious Diseases notified during the year; Table IV., Causes of, and Ages at, Death during the year; Table V., Infantile Mortality during the year; Deaths from stated causes in weeks and months under one year of age. Part 3 summarises the vital statistics and sanitary work for the period. The Criccieth urban district is situated in the Pwllheli Union, and Pwllheli registration district and in the Criccieth registration subdistrict, and has an area, exclusive of area covered by water, of 472 statute acres. The population, estimated to June, 1910, is 1402. In England and Wales the birth-rate, death-rate, and infantile mortality were 24·8, 13·4, and 106 respectively, each of these being the lowest on record. Dr. Lloyd Owen's report shows a birth-rate of 8·55 per 1000 of population, which was lower by 16·25 than that in England and Wales, lower by 9·98 than that in the previous year, and lower by 10·95 than the average rate in the preceding 10 years. The death-rate, 12·12, however, is lower by 1·28 than that in England and Wales, and by 3·78 than the average rate in the preceding 10 years.

[1] See also THE LANCET, Sept. 2nd, 1911, p. 726.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns, having an estimated population of 16,157,797 persons in the middle of this year, 7463 births and 4388 deaths were registered during the week ending Nov. 25th. The annual rate of mortality in these towns, which had been 13·5, 13·1, and 13·9 in the three preceding weeks, further rose to 14·2 per 1000 in the week under notice. During the first eight weeks of the current quarter the mean annual rate of mortality in these towns averaged 14·1 per 1000, while the average death-rate in London during the same period did not exceed 13·7. The death-rates in the 77 towns last week ranged from 4·9 in Hornsey, 6·2 in Newport (Mon.), 6·6 in Wallasey, and 7·3 in Barrow-in-Furness, to 19·3 in Wigan, 20·1 in Burnley, 20·6 in West Bromwich, and 22·0 in Stockton-on-Tees. The 4388 deaths from all causes in the 77 towns were 69 in excess of the number registered in the preceding week, and included 259 which were referred to the principal epidemic diseases, against numbers steadily decreasing from 2900 to 267 in the 13 preceding weeks. Of these 259 deaths, 73 resulted from infantile diarrhœa, 61 from diphtheria, 44 from measles, 32

from whooping-cough, 29 from scarlet fever, and 20 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases last week did not exceed 0·8 per 1000, and was the lowest death-rate from these diseases recorded in any week of the current year. The deaths of infants under two years of age attributed to diarrhœa, which had steadily declined from 2714 to 76 in the 13 preceding weeks, further fell to 73 last week, and included 24 in London and its suburban districts, 4 each in Stoke-on-Trent, in Birmingham, and in Cardiff, and 3 each in Liverpool, in Bolton, in Manchester, and in Oldham. The deaths referred to diphtheria, which had increased from 46 to 64 in the four preceding weeks, declined to 61 last week; 21 deaths were recorded in London and its suburban districts, 5 in Leeds, and 3 each in Stoke-on-Trent, in Bolton, and in Bradford. The fatal cases of measles, which had been 36, 37, and 51 in the three previous weeks, declined to 44 last week, and of this number 9 were registered in London, 4 each in Nottingham, in Salford, and in Burnley, 3 in Wolverhampton, and 3 in West Bromwich. The 32 deaths assigned to whooping-cough were 1 in excess of the number in the preceding week, and included 9 in London and its suburban districts, 6 in Birmingham, 2 in Smethwick, and 2 in Liverpool. The deaths attributed to scarlet fever, which had declined from 30 to 21 in the three preceding weeks, rose again to 29 last week; 4 deaths occurred in Stoke-on-Trent, 3 in London, and 2 each in Birmingham, Liverpool, Sheffield, Hull, and Newport, Mon. The 20 deaths referred to enteric fever were 4 less than the number recorded in each of the two previous weeks, and included 6 in London and its suburban districts, and 2 each in Birmingham, Leeds, and Newcastle-on-Tyne. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily increased from 1327 to 2213 in the 12 preceding weeks, declined to 2166 on Saturday last; 203 new cases of this disease were admitted to these hospitals during the week, against 269, 292, and 291 in the three preceding weeks. These hospitals also contained on Saturday last 1311 cases of diphtheria, 171 of whooping-cough, 101 of enteric fever, and 73 of measles. The 1146 deaths from all causes in London last week were 18 in excess of the number in the previous week, and included 243 which were referred to diseases of the respiratory system, against 170, 196, and 224 in the three previous weeks. The deaths attributed to different forms of violence in the 77 towns, which had been 144, 136, and 167 in the three preceding weeks, declined to 158 last week, and 374 inquest cases were registered. The causes of 33, or 0·8 per cent., of the deaths registered in the 77 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Sheffield, Leeds, Bradford, Hull, Nottingham, Portsmouth, and in 56 other smaller towns. The 33 uncertified causes of death last week included 7 in Birmingham, 6 in Liverpool, 5 in London, 3 in South Shields, and 3 in Gateshead.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 767 births and 548 deaths were registered during the week ending Nov. 25th. The annual rate of mortality in these towns, which had been 16·3 and 18·6 in the two preceding weeks, declined to 16·7 per 1000 in the week under notice. During the first eight weeks of the current quarter the mean annual death-rate in these Scotch towns averaged 16·5 per 1000, and was 2·4 per 1000 above the mean rate during the same period in the 77 large English towns. The annual death-rates in the several Scotch towns last week ranged from 10·3 and 10·5 in Leith and in Paisley to 18·8 in Glasgow and in Aberdeen. The 548 deaths from all causes were 63 fewer than the number in the previous week, and included 63 which were referred to the principal epidemic diseases, against 48 and 65 in the two preceding weeks; of these 63 deaths, 23 resulted from measles, 16 from diarrhœal diseases, 7 from scarlet fever, 7 from whooping-cough, 7 from diphtheria, 2 from enteric fever, and 1 from typhus fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 1·9 per 1000, and was 1·1 per 1000 above the mean rate from the same diseases in the 77 large English towns. The deaths referred to measles, which had steadily increased from 1 to 28 in the eight preceding weeks, declined to 23 last week, and comprised 14 in Aberdeen, 7 in Glasgow, and 2 in Greenock. The deaths attributed to diarrhœal diseases, which had been 12, 9, and 19 in the three previous weeks, fell last week to 16, all but one of which related to children under two years of age; 5 deaths were recorded in Glasgow, 4 in Edinburgh, 3 in Dundee, and 2 in Greenock. The 7 fatal cases of scarlet fever were 4 in excess of the average in the three preceding weeks, and included 3 deaths in Glasgow. The deaths assigned to whooping-cough, which had been 11, 14, and 8 in the three previous weeks, slightly fell to 7 last week, and comprised 4 in Glasgow, 2 in Aberdeen, and 1 in Edinburgh. The deaths referred to diphtheria, which had been 9 and 4 in the two preceding weeks, rose to 7 last week, and included 4 in Glasgow, 2 in Dundee, and 1 in Greenock. The 2 fatal cases of enteric fever and also that of typhus fever were registered in Glasgow. The deaths referred to diseases of the respiratory system, which had been 116, 108, and 144 in the three preceding weeks, declined to 113 last week, and was 25 below the number in the corresponding week of last year. Of the 548 deaths from all causes in the Scotch towns last week, 165, or 30 per cent., were recorded in public institutions, and 31 were attributed to different forms of violence. The causes of 24, or 4·4 per cent., of the deaths in the eight towns in the week under notice were not certified or not specified; in the 77 large English towns the proportion of uncertified causes did not exceed 0·8 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 534 births and 396 deaths were registered during the week ending Nov. 25th. The annual rate of mortality in these towns, which had increased from 17·1 to 19·0 in the four preceding weeks, declined to 18·0 per 1000 in the week under notice. During the first eight weeks of the current quarter the mean annual death-rate in these Irish towns averaged 18·3 per 1000; in the 77 large English towns the mean annual death-rate during the same period did not exceed 14·1 per 1000, while in the eight Scotch towns it was equal to 16·5. The annual death-rate last week was equal to 20·3 in Dublin (against 13·2 in London), 17·3 in Belfast, 17·7 in Cork, 5·1 in Londonderry, 10·9 in Limerick, and 15·2 in Waterford; whilst in the 16 smallest of these Irish towns the annual death-rate was equal to 19·3 per 1000. The 396 deaths from all causes were 23 fewer than the number in the previous week, and included 44 which were referred to the principal epidemic diseases, against 33 and 47 in the two preceding weeks; of these 44 deaths, 19 resulted from diarrhœal diseases, 11 from whooping-cough, 5 from scarlet fever, 4 from measles, 3 from enteric fever, and 2 from diphtheria, but not one from small-pox. These 44 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·0 per 1000; in the 77 English towns the mean annual death-rate from these diseases last week did not exceed 0·8 per 1000, while in the eight Scotch towns it was equal to 1·9. The deaths attributed to diarrhœal diseases, which had been 24, 9, and 19 in the three preceding weeks, were again 19 last week, and with one exception related to children under 2 years of age; 7 deaths were recorded in Dublin, 7 in Belfast, and 3 in Cork. The deaths referred to whooping-cough, which had been 2 and 5 in the two previous weeks, rose to 11 last week, and included 5 in Belfast, 3 in Dublin, and 2 in Lurgan. The 5 fatal cases of scarlet fever were slightly in excess of the average in recent weeks, and comprised 2 in Dublin, 2 in Belfast, and 1 in Waterford. The deaths assigned to measles, which had been 9 and 8 in the two preceding weeks, further declined last week to 4, and were all registered in Dublin. Two of the fatal cases of enteric fever were recorded in Dublin and 1 in Newry. The 2 deaths referred to diphtheria occurred in Newry and Sligo respectively. The deaths referred to diseases of the respiratory system, which had been 77, 75, and 73 in the three preceding weeks, rose to 78 last week. Of the 396 deaths from all causes in the Irish towns last week, 138, or 35 per cent., were recorded in public institutions, and 13 were attributed

to different forms of violence. The causes of 14, or 3·5 per cent., of the deaths in the 22 towns in the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes last week did not exceed 0·8 per cent. in the 77 large English towns, but was equal to 4·4 per cent. in the eight Scotch towns.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned surgeons have been promoted to the rank of Staff-Surgeon in His Majesty's Fleet: Walter Perceval Yetts, Thomas Dixon Liddle, Norman Sinclair Meiklejohn, William Perceval Hingston, Reginald Hugh St. Bernard Ellis Hughes, Frederick Morton Vincent Smith, Arthur Henry Sims Richardson, George Herbert Stephens Milln, Edward Bryan Kenny, Arthur Reginald Schofield, Francis Jollie Gowans, Evelyn Richard Townsend, James Campbell Bringan, Guy Leslie Buckeridge, Arthur Dillon Croker Cummins, Thomas Walter Jeffery, Palmer Devoy Ramsay, Edward Postle Gwyn Causton, George Deleval Walsh, James Ernest Johnston, and Bertram Raleigh Bickford (dated Nov. 23rd, 1911).

ARMY MEDICAL SERVICE.

Colonel Sir David Bruce, C.B., is seconded for service under the Colonial Office (dated Nov. 9th, 1911). Lieutenant-Colonel William W. Pike, D.S.O., from the Royal Army Medical Corps, to be Colonel, vice Sir D. Bruce, C.B., seconded (dated Nov. 9th, 1911).

ROYAL ARMY MEDICAL CORPS.

Major David Harvey is seconded for service under the Colonial Office (dated Nov. 9th, 1911).

Lieutenant-Colonel J. M. Irwin, senior medical officer at Tientsin, has been appointed Principal Medical Officer of South China, with headquarters at Hong-Kong, vice Colonel W. G. A. Bedford, C.M.G., transferred to the London District as Principal Medical Officer. Lieutenant-Colonel H. L. Battersby, from Bodmin, has been appointed to the Medical Charge of the Royal Horse Artillery Batteries at Ipswich. Lieutenant-Colonel E. Davis has taken up duty in Medical Charge at St. Peter's, Jersey. Lieutenant-Colonel A. Dodd, senior medical officer at Chester, has been removed from the roster for foreign service. Lieutenant-Colonel J. C. Morgan has taken over charge of the Military Hospital at Glasgow. Lieutenant-Colonel A. E. Tate has been selected to command the Station Hospital at Rawal Pindi, vice Lieutenant-Colonel M. O. D. Braddell, tour expired. Lieutenant-Colonel R. L. R. MacLeod, from Aden, has been appointed for duty on board the troopship s.s. *Plassy*, which left Bombay on Nov. 9th for Southampton. Lieutenant-Colonel J. J. C. Donnet, in medical charge of the Military Hospital at Belfast, has taken up duty as Senior Medical Officer at Singapore, vice Lieutenant-Colonel H. J. Barratt, who has been transferred to India. Lieutenant-Colonel F. H. M. Burton has been placed under orders for transfer from Colchester to Warley to fill the vacancy caused by the retirement of Lieutenant-Colonel T. W. O'H. Hamilton. Major R. J. Copeland has been transferred from Darjeeling to the Station Hospital at Meerut Cantonment. Major B. Forde, from Aldershot, has taken over the medical charge at Deepcut. Major A. Chopping, staff surgeon at Cherat, has been placed under orders to proceed home, tour expired, from India on the troopship s.s. *Rewa*, leaving Karachi on Dec. 9th. Major F. Smith, D.S.O., sanitary officer of the Second (Rawal Pindi) Division, has taken over charge of the Station Hospital at Calcutta, vice Lieutenant-Colonel T. McCulloch. Major H. O. B. Browne-Mason has been appointed Specialist in Dermatology and Venereal Diseases to the Sixth (Poona) Division. Major H. K. Palmer, specialist in advanced operative surgery at Meerut, has been granted six months' leave of absence. Major E. W. Slayter has been appointed to command the Station Hospital at Mount Abu for a period of two years. Captain R. R. Argles, from Lahore, has been detailed for duty on board the troopship ss. *Plassy*, which left Bombay for Southampton on Nov. 9th. Captain B. B. Hole, from Cosham, has joined the Scottish Command for duty as Adjutant of the Royal Army Medical Corps School of Instruction, Lowland Division. Captain A. F. Carlyon, from Devonport, has embarked for a tour of service at Mauritius. Captain W. J. Waters has taken up duty in North China. The leave of absence home from India granted to Captain H. W. Farebrother has been extended on the recommendation of a medical board. Captain A. J. Williamson, specialist in advanced operative surgery, from Woolwich, has embarked for a tour of service at Singapore. Captain R. C. Wilson, in charge of the Military Families Hospital at Netley, has been placed under orders for a tour of service at Gibraltar. Captain R. H. MacNichol, specialist in dermatology and venereal diseases, has taken over charge of the Military Hospital at Northampton during the absence on leave of Lieutenant-Colonel W. S. Dowman. Captain R. J. B. Buchanan has been selected for appointment as Clinical Pathologist to the Alexandra Hospital at Cosham. Captain F. W. W. Dawson has been detailed for a tour of service with the Third (Lahore) Division, Northern Army in India. Captain G. B. F. Churchill has been granted one year's extension of service in India. Captain F. E. Rowan-Robinson has been granted one month's leave of absence prior to embarkation for duty in Bermuda. Captain P. G. Hyde has joined for duty at Ceylon. Captain R. N. Woodley has been transferred from Bulford Camp, Salisbury Plain, to the Military Hospital at Cardiff. Captain J. M. M. Crawford, from Colchester, has taken up duty at Ipswich as Adjutant of the Royal Army Medical Corps School of Instruction, East Anglian Division, in succession to Major W. A. Woodside, under orders for India. Lieutenant M. White, from Bordon, has embarked for duty with the Eighth (Lucknow) Division, Northern Army in India. Lieutenant P. G. M. Elvery, from Cairo, has taken up duty at Cyprus. Lieutenant J. K. Gaunt, from Lisnagar Camp, has been appointed to Fermoy. Lieutenant W. P. MacArthur, from Aldershot, has embarked for a tour of service in Mauritius. Lieutenant A. T. J. McCreery, from the Station Hospital at Mhow, has been appointed for duty at Indore. Lieutenant C. T. V. Benson, at present serving at Aldershot, has been placed under orders for service in Burma.

INDIAN MEDICAL SERVICE.

The King has approved of the promotion of Captain Edward Owen Thurston to Major (dated July 27th, 1911).

Colonel W. A. Corkery, Principal Medical Officer, Lahore Division, has been granted three months' leave of absence. The Lieutenant-Governor of the Punjab has been pleased to appoint Lieutenant-Colonel D. T. Lane to be a Civil Surgeon of the First Class in succession to Lieutenant-Colonel J. A. Cunningham. Lieutenant-Colonel B. C. Oldham, Bengal Presidency, has arrived home on leave of absence. Lieutenant-Colonel W. Ronaldson Clarke has been appointed Civil Surgeon at Lahore, and Professor of Forensic Medicine at the Government Medical College, Lahore, on return from privilege leave, relieving Captain H. C. Keates, transferred. Lieutenant-Colonel D. M. Davidson has been selected for appointment as Medical Officer in charge of the Punjab Central Camp in the Coronation Durbar at Delhi. Lieutenant-Colonel C. E. L. Gilbert has been granted four months' extension of his leave of absence home from India by the Right Honourable the Secretary of State on the recommendation of a Medical Board. The services of Lieutenant-Colonel B. B. Grayfoot have been replaced by the Home Department of the Government of India at the disposal of the Bombay Government. Lieutenant-Colonel A. W. T. Boist has been appointed a Civil Surgeon of the First Class. Lieutenant-Colonel W. H. Gray, Superintendent of the Central Prison at Benares, United Provinces, has been granted leave of absence from India for two years. Major F. D. Blenkinsop has embarked for India on the expiration of his leave. Major F. Wall has been granted furlough for one year. Major A. W. R. Cochrane, superintendent of the lunatic asylum at Agra, has been granted six months' leave of absence. Major C. E. Williams, Bengal Presidency, has received an extension of his leave. Major H. Bennett has been appointed to officiate as a Civil Surgeon of the First Class, *vice* Lieutenant-Colonel C. T. Hudson, on leave. His Excellency the Governor of Bombay, in Council, has been pleased to appoint Major G. E. Stewart to officiate as Civil Surgeon at Dhulia, in succession to Captain R. F. Steel. Captain G. Holroyd has been selected to officiate as Superintendent of the Central Jail at Bhagalpur, in succession to Major J. M. Woolley, appointed Senior

Medical Officer at Port Blair. Captain S. H. Lee Abbott and Captain J. G. G. Swan have been appointed Civil Surgeons of the Second Class. Subsequent on the transfer of Colonel H. Hendley to the Military Department, Captain H. C. Buckley has been appointed Plague Medical Officer at Rohtak, on transfer from special duty under the Government of India. Captain E. T. Harris has been granted four months' extension of his leave of absence. Captain E. A. Roberts and Captain J. F. James have embarked for India. Captain H. C. Keates has been selected for appointment as Civil Surgeon at Jullundur. Captain J. M. A. Macmillan, civil surgeon at Hoshangabad, has been appointed to the medical and sanitary charge of the Central Provinces Camps at the Delhi Coronation Durbar. Lieutenant P. B. Bharucha has been appointed Surgical Specialist to the Second (Rawal Pindi) Division in succession to Lieutenant C. H. Smith.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Charles H. Carlton is confirmed in his rank.

TERRITORIAL FORCE.

Royal Engineers.

5th and 6th Battalions, The Royal Warwickshire Regiment: Surgeon-Captain George H. E. Bekenn resigns his commission (dated Nov. 25th, 1911).

Royal Army Medical Corps.

1st West Lancashire Field Ambulance, Royal Army Medical Corps: The undermentioned officers to be Captains (dated Oct. 1st, 1911):—Lieutenant John E. W. MacFall, Lieutenant Richard S. Taylor, Lieutenant Adam P. H. Simpson.

2nd West Lancashire Field Ambulance, Royal Army Medical Corps: The undermentioned officers to be Captains (dated Oct. 1st, 1911):—Lieutenant Charles S. Brebner, Lieutenant Walker L. Hawksley, and Lieutenant William Macdonald.

2nd Northumbrian Field Ambulance, Royal Army Medical Corps: Lieutenant James D. Sinclair to be Captain (dated Oct. 1st, 1911).

3rd West Riding Field Ambulance, Royal Army Medical Corps: The undermentioned officers to be Captains:—Lieutenant John W. Stokes (dated Oct. 1st, 1911), Lieutenant James Mackinnon (dated Oct. 1st, 1911), Lieutenant Ernest F. Finch (dated Oct. 6th, 1911), Lieutenant Charles G. Murray (dated Oct. 10th, 1911), and Lieutenant Edward F. Skinner (dated Oct. 11th, 1911).

3rd Wessex Field Ambulance, Royal Army Medical Corps: Lieutenant John A. Swindale resigns his commission (dated Nov. 25th, 1911).

2nd Scottish General Hospital, Royal Army Medical Corps: Major Robert W. Philip to be Lieutenant-Colonel (dated Sept. 15th, 1911). Captain Francis D. Boyd, C.M.G., to be Major (dated Sept. 15th, 1911). John William Simpson to be Captain (dated Sept. 15th, 1911).

Attached to Units other than Medical Units.—Major and Honorary Surgeon-Lieutenant-Colonel Duncan Stewart resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated Nov. 25th, 1911).

For Attachment to Units other than Medical Units.—Geoffrey Balmanno Fleming to be Lieutenant (dated Sept. 22nd, 1911).

Supernumerary for Service with the Officers Training Corps.—Captain Henry Buckley Roderick, from the Unattached List for the Territorial Force, to be Captain, with precedence as on the Unattached List, for service with the medical unit of Cambridge University Contingent, Senior Division, Officers Training Corps (dated Nov. 25th, 1911). Captain William Duncan Sturrock, from the Unattached List for the Territorial Force, to be Captain, with precedence as on the Unattached List, for service with the medical unit of the Oxford University Contingent, Senior Division, Officers Training Corps (dated Nov. 25th, 1911). Lieutenant Rudolf Albert Peters, from the List of Officers of the Royal Army Medical Corps attached to units other than medical units, to be Lieutenant (on probation), with precedence as in the Territorial Force, for service with the medical unit of the Cambridge University Contingent, Senior Division, Officers Training Corps (dated Nov. 25th, 1911). Andrew Francis Dixon to be Lieutenant, for service with the medical unit of Dublin University Contingent, Senior Division, Officers Training Corps (dated Sept. 23rd, 1910). Thomas Thomson to be Lieutenant, for service with the Royal College of Surgeons in Ireland Contingent, Senior Division, Officers Training Corps (dated April 7th, 1911). Henry Stokes to be Lieutenant, for service with the Royal College of Surgeons in Ireland Contingent, Senior Divison, Officers Training Corps (dated April 29th, 1911). William James Wilson to be Lieutenant, for service with the medical unit of the Belfast University Contingent, Senior Division, Officers Training Corps (dated May 25th, 1911).

Officers Training Corps.

Oxford University Contingent, Senior Division, Officers Training Corps: Lieutenant William D. Sturrock to be Captain (dated Oct. 26th, 1911).

Yeomanry.

Northumberland (Hussars) Yeomanry: Surgeon-Lieutenant Hamilton Drummond resigns his commission (dated Nov. 25th, 1911).

THE ROYAL NAVAL VOLUNTEER RESERVE.

The regulations concerning medical officers in this service have just been issued. Candidates for entry must not be over 32 years of age, and if accepted will be enrolled with the rank of Surgeon. There are 8 fleet-surgeons, 22 staff-surgeons, and 120 surgeons in the service. Application for entry should be made to the Admiralty Volunteer Committee, Whitehall, S.W.

HEALTH OF THE UNITED STATES ARMY.

The report of the Surgeon-General of the United States Army for the year 1910, which has just been issued, contains much interesting matter. The figures relating to the admission of soldiers to army hospitals for alcoholism show that in 1910 the rate was 23·51 per 1000. In 1900 it was 25 per 1000. In the ten years before the establishment of the canteen the average rate of admission was 55 per 1000; it fell to an average of 26 per 1000 while the canteen existed, and rose to 28 per 1000 in the ten years following its abolition. The improvement in the alcoholic rate began before the establishment of the canteen and continued during the greater part of the canteen period, in correspondence with the general progress of temperance. It would probably have been sustained but for the abolition of the canteen, which destroyed the attractiveness of the soldier's club and drove him outside for amusement, where he was tempted to drink strong drinks to excess in place of mild fermented liquors in moderation. 16,093 vaccinations against typhoid fever took place. The outstanding feature of the report in regard to anti-typhoid vaccination is the fact that only three of the vaccinated men became infected with typhoid fever. The disease in each case ran a mild course and recovery was rapid. The vital statistics indicate a steady improvement in the health of the soldiers. The ratios were 596·54 admissions to hospital, 3·4 deaths, and 28·35 rendered non-effective per 1000 in 1910, as compared with 628·91, 4·20, and 30·27 per 1000 respectively in 1909. The mean strength of officers was 4416, of which number 37, or 8·38 per 1000, were retired for disabilities in 1910, as compared with 19·21 for 1909. The mean strength of rank and file for 1910 is given as 71,534, as compared with 74,319 for 1909, and the discharge-rate for disability was 14·02 per 1000.

HOSPITAL ALMONERS' COUNCIL.—The inaugural meeting of the newly constituted Hospital Almoners' Council was held at Caxton Hall on Nov. 24th, the Bishop of Stepney, Vice-President, being in the chair. The Council has considerably increased its membership, and now includes 16 representatives of the governing bodies and medical staffs of 12 London hospitals. The heads of women's colleges in Oxford, London, and Dublin have also joined the Council, together with hospital almoners working in London, and others interested in the movement. The Council will continue to select and train women for almoners' posts, and to recommend them to hospitals. At the meeting a constitution was adopted and an executive committee was chosen. The speakers were Mr. C. S. Loch (the founder of the movement), Sir Edward Brabrook (Vice-President), Dr. R. Hutchison, Dr. T. W. Eden, and Dr. A. Chas E. Gray (former chairman of the Council). All communications with regard to this excellent work should be addressed to Mr. Edgar S. Kemp, at Denison House, 296, Vauxhall Bridge-road, London, S.W.

Correspondence.

"Audi alteram partem."

BICENTENARY OF THE SCHOOL OF PHYSIC OF IRELAND: JUNE, 1912.

To the Editor of THE LANCET.

SIR,—We are asked to draw attention to the proposed celebration of the bicentenary of the School of Physic in Ireland. This school, better known now as the Medical School of Trinity College, Dublin University, was founded early in the eighteenth century under the joint control of the University and the King and Queen's College of Physicians. The management of the school has been for some time past practically altogether in the hands of the Universities authorities, but the school still retains its old name and some of its most important professors are appointed by the College of Physicians.

A provisional committee has been appointed to make arrangements for the celebrations to be held at the end of June, 1912, and this committee is most anxious to receive suggestions from graduates who are willing to coöperate. A graduates committee will shortly be formed, and those who are willing to become members are invited to send in their names. The provisional committee is most anxious to receive loans of documents or other objects of interest which may illustrate the history of the school, and will be glad to hear from anyone who may possess such objects. All who are willing to assist are requested to communicate with any of the undersigned.

We are, Sir, yours faithfully,

JAMES LITTLE, M.D. Edin.,
Regius Professor of Physic.
CHARLES BALL,
Regius Professor of Surgery.
A. C. O'SULLIVAN, F.T.C.D.,
University Lecturer in Pathology.
W. H. THOMPSON, M.D. R.U.I.,
King's Professor of the Institutes of Medicine.
JAMES CRAIG, M.D. Dub.,
King's Professor of the Practice of Medicine.
T. PERCY C. KIRKPATRICK, M.D. Dub.,
A. FRANCIS DIXON, Sc.D. Dub.,
University Professor of Anatomy.

Nov. 27th, 1911.

THE NATIONAL INSURANCE BILL.

To the Editor of THE LANCET.

SIR,—At a largely attended meeting of the West Croydon and District Medico-Ethical Society the following resolution was agreed to unanimously, and I was instructed to forward the same to you for insertion in THE LANCET:—

That this meeting refuses to act under the Insurance Bill unless the six cardinal points are definitely and emphatically conceded. It further is of opinion that payment *per capita* is absolutely undesirable, and it will only consider the scheme if payment per attendance on satisfactory terms is guaranteed by the Local Health Committee. And, further, it is also of opinion that the medical representation on the Local Health Committee, as at present suggested, is altogether insufficient.

I am, Sir, yours faithfully,
WILLIAM V. BRADDON, Hon. Secretary.

Thornton Heath, Nov. 22nd, 1911.

*** We have received a large number of letters from medical men registering disapproval of the National Insurance Bill upon one or other of the many counts familiar to all our readers, as well as communications from local correspondents (see p. 1581). These confirm us for different reasons in the opinions expressed in our leading article.—ED. L.

THE CAUSE OF CANCER.

To the Editor of THE LANCET.

SIR,—Having regard to the views and claims advanced by Sir Henry Butlin in his recent lectures I am induced to invite his and his readers' attention to the thesis I put forward on this question so long ago as 1888 (THE LANCET, August 25th, p. 395, "In what does Cancer Consist?"), and more recently in the *British Medical Journal* of Dec. 26th, 1903. These views have received corroboration by the work of Messrs. Farmer, Moore, and Walker, published in the Proceedings of the Royal Society, 1903, wherein reference is made to my suggestions of 23 years ago.

I am, Sir, yours faithfully,
WILLIAM J. COLLINS.

Albert-terrace, Regent's Park, N.W., Nov. 27th, 1911.

MINER'S PHTHISIS.

To the Editor of THE LANCET.

SIR,—"Sooner or later every worker underground on these mines will contract miner's phthisis." These words were uttered before a representative meeting of mining engineers in Johannesburg on Sept. 9th, 1911, by Mr. Koetze, the Government mining engineer.

The number of white workers roughly at the present time going below is about 12,000 and the black about 150,000. The death-rate at the present time is appalling. What will it be in a few years? I refer your readers to the following paragraph in a letter from the well-known consulting engineer, Mr. E. J. Moynihan:—

The Mining Regulations Commission (Transvaal) of 1907-1910, of which Dr. Porter, M.O.H., of Johannesburg, was the medical member, practically finished taking evidence in June, 1908. Its report was not signed till March, 1910; and not issued till August, 1910, more than two years after practically all the evidence was in. Part of the work of this commission was to investigate the health of mining employees. Their figures show a death-rate, from *all* forms of phthisis, of about 11 per 1000 for the underground men. That this is entirely below the mark and based on wholly insufficient inquiry and data is now proved by the experience of the present duplicate Commission appointed (1) to examine the miners' lungs, and (2) to award temporary compensation.

Since three men per day are putting in valid applications for compensation, and are, most of them, in the last extremity and have only recently left work, it is clear that there either now are, or will be in the very near future, 1000 deaths annually from miner's phthisis (silicosis). This corresponds to a silicosis death-rate among the underground white men (about 12,000 in number) of over 80 per 1000 annually. The disease is mainly prevalent among the "machine men" (rock-drillers) who form less than half of the underground white employees. The machine-men therefore have a death-rate, from silicosis only, of probably more than 140 per 1000. This is an understatement, in effect, of the real truth, because the number of machines in use has increased more than 75 per cent. in the last two years. A large proportion of the men have therefore been exposed to risk for too short a time to produce any sensible proportion of the deaths. If this fact be dealt with by a rough correction factor, the corrected death-rate for machine-men from this one disease alone would be well over 230 per 1000. Such a death-rate from a single occupational disease must be unparalleled in the whole industrial world. It can only be compared with King Leopold's Congo Free State.

It is with the view of bringing directly to the notice of the home Government and your readers the present very serious state of affairs that I have sent you this letter, which, though necessarily omitting many details, gives the facts up to date.

Some nine years ago a letter was forwarded to THE LANCET pointing out the grave danger of this disease. Acting upon this letter Mr. Chamberlain ordered an inquiry, and the Miner's Phthisis Commission of 1902 was appointed. The commission did its work well, established the cause of the disease, and pointed out the remedy. A feeble attempt on the part of the mine-owners to do something was the result, and nothing more. In 1908 another commission was formed with a like result. This year another commission has been promoted. Beyond the fact that the Government mining engineer is enabled to make the first statement in this letter, no good has accrued from any of these commissions. The chairman of the first commission and several members and witnesses are all dead from the disease. Each commission recommends the use of water to keep down the dust which causes the disease, the recommendations are urged upon the mine-owners, and with the same results in each case—utter callousness and neglect.

To-day we are faced with such a truly appalling state of affairs that it is a very pertinent question whether the whole gold industry of the Rand shall not be closed down until the mine-owners are prepared to put their mines in order and give guarantees for the future. In spite of all the protestations of the mine-owners to the contrary, those of us who are in a position to know can truly say that with one or two exceptions the water-supply to the mines is a sham and a farce not worthy of the name. The argument that men will not use the means given them has now been dispelled.

Upon the Nanse mines it has been proved that with a proper system of supervision men can be brought under discipline as well below ground as above. Yet knowing these facts days and weeks roll by, whilst the mine-owners are supposed to be considering the matter, and the Government ditto.

I regret to say that, however estimable these gentlemen may be in private life, their attitude with regard to putting their house in order is difficult to express in words. There is not an extenuating circumstance to be urged on their behalf. They, and they alone, can make a serious beginning of stopping this disease by adopting the system so successful in the Nanse mines. But, no; they will wait until public opinion or the Home Government forces the local government here to inflict the severest compensation measures upon them. These gentlemen will then appeal for mercy on the grounds that the industry will be ruined. These gentlemen won't do anything so foolish as to allow the industry to be ruined. We all know that imagination is very largely essential to the ruining of a gold mine, but I regret to say that only one argument appeals to the mine magnate in dealing with life preservation, and that argument is to make him pay.

I am, Sir, yours faithfully,
J. L. AYMARD, M.R.C.S. Eng., L.R.C.P. Lond.

Johannesburg, Sept. 19th, 1911.

TWO RARE ABNORMALITIES OBSERVED IN THE COURSE OF OPERATIONS.

To the Editor of THE LANCET.

SIR,—In your issue of Nov. 18th Mr. J. D. Malcolm, drawing attention to a rare and interesting case under this title, characterised by a single mesentery and abnormal position of the large intestine, states that he believes that this condition has not been before described. I, however, reported a similar case in the *Durham College of Medicine Gazette* of March, 1908, and my drawing of the parts is exactly similar to that in Mr. Malcolm's article. Mr. Jonathan Hutchinson, in the *Clinical Journal*, June 5th, 1907, describes ten cases of complete volvulus of the intestine where also a somewhat similar arrangement of the mesentery existed, and I have also references to other examples. In these cases developmental rotation of the intestine had not occurred, resulting in an arrangement which is found in some of the pronograde animals. Apart from appendicitis arising on the left side, this disposition of the mesentery allows extensive volvulus to occur, the whole bowel from the duodenum to the descending colon being involved. In the case reported by me the volvulus was reduced, and the patient recovered. The further history of this patient has not been published, but two recurrences took place, both of which were relieved by abdominal section and reduction. This case was seen at the Royal Victoria Infirmary, Newcastle-on-Tyne, during my house surgeoncy.

I am, Sir, yours faithfully,
Newcastle-on-Tyne, Nov. 26th, 1911. FREDERICK C. PYBUS.

To the Editor of THE LANCET.

SIR,—I am much interested in Mr. John D. Malcolm's case of malposition of the large intestine as described under this title in THE LANCET of Nov. 18th, p. 1401. I have recently had a similar case, discovered during X ray examination after bismuth feeding in the routine investigation of an abdominal case of Mr. Moynihan. The cæcum was situated just above the symphysis pubis and a little to the left of the middle line. The colon ascended on the left side to a point about the level of the splenic flexure. The "transverse" colon was represented by a loop descending to the level of the umbilicus and rising again to the splenic flexure. The descending colon was normal in position.

In Mr. Malcolm's case no transverse colon is represented and it would be interesting to know if it was in the form of a loop as in my case. This could be easily decided by X ray investigation.

I am, Sir, yours faithfully,
LEO. A. ROWDEN, M.B., C.M. Glasg.

Leeds, Nov. 25th, 1911.

SYPHILITIC AUTO-REINFECTION.

To the Editor of THE LANCET.

SIR,—Without wishing in any way to criticise the general tenour of Major French's recent Hunterian lectures on Syphilis—*quot homines, tot sententiæ*—I would like to draw attention to a statement on p. 1385 which, as quoted, is entirely misleading. He says: "Mr. McDonagh states that he has had 3 cases within the last 12 months of men early in the secondary stage cured by salvarsan return with a diffuse macular rash ..... which appeared a few weeks after the patient noticed the site of his original sore swell and become red." The crux of the whole argument is here omitted, and if the original be read (*British Medical Journal*, Sept. 23rd, 1911, p. 678) the following completes my sentence: "Which, by the way, is a very rare recurrent syphilide." I might even have been a little stronger, since I have never seen a case where six weeks after a swelling and redness of the chancre the patient developed a polyadenitis and a rash all over the body indistinguishable from the primary rash which had followed the chancre only a few months back. The explanation is simple. As a result of the "606" all the spirochætæ in the body have been destroyed except in the chancre, owing to the drug not having reached them in sufficient quantity; because they are shut up in fibrous, non-vascular tissue, a sequence of the induration. As a result of external irritation or because there are no antibodies present these imprisoned organisms "wake up," multiply, and are capable of giving rise to a fresh infection. This is a strong argument in favour of the advisability of excising a chancre which I have advocated for a long time, and also demonstrates that there is no such thing as absolute syphilitic immunity either to a foreign or a home virus. In consequence of there being no immunity the three patients referred to developed another general infection, as shown by the polyadenitis, macular rash, and reappearance of a positive Wassermann. Therefore, such cases are not relapses in the true sense of the word, and Major French could never have put them down as such, since he has probably never seen a similar case and admits that he has never used "606."

Excising the chancre and giving two intravenous injections of salvarsan before the Wassermann's reaction is positive—i.e., before the stage of general infection is reached—is practically a certain cure in my opinion. I have had 29 cases treated in this manner in the last 16 months, in which the Wassermann's reaction is still negative and the patients have been free from all symptoms. Surely this speaks for the efficiency of salvarsan—also mentioned in above number of *British Medical Journal* but omitted in Major French's lectures.

Last June I showed a case of auto-reinfection after a long period had elapsed since the primary infection at the Dermatological Section of the Royal Society of Medicine.[1] The patient contracted syphilis in 1905, and under mercurial treatment all the symptoms disappeared except the induration of the chancre. The induration persisted for six years when, as a result of irritation, erosions appeared on the surface, and six weeks later the glands of the body became enlarged. The patient was covered with a macular rash and had a sore throat. Contrary to the general belief, induration may persist for a considerable period irrespective of how much mercury the patient has had.—I am, Sir, yours faithfully,

J. E. R. MCDONAGH, F.R.C.S. Eng.

Harley-street, W., Nov. 24th, 1911.

SPECIAL RETURN OF PAUPERS UNDER MEDICAL TREATMENT.

To the Editor of THE LANCET.

SIR,—Acting on behalf of the Council of the Poor-Law Medical Officers' Association of England and Wales I have approached the Local Government Board on the above subject.

May I ask you to give publicity to the enclosed copies of the correspondence?

I am, Sir, yours faithfully,
MAJOR GREENWOOD, Honorary Secretary.

[ENCLOSURE.]

34, Copthall-avenue, E.C., Nov. 11th.

Secretary, Local Government Board—

Special Return of Paupers under Medical Treatment.

SIR,—On Oct. 27th last a circular was issued by the Local Government Board to boards of guardians in England and Wales asking for a special return of paupers under medical treatment. In consequence, a request has been made by the clerks of the various unions to the district medical officers throughout the country to furnish a considerable number of details, at the cost of much time and labour.

It is generally thought throughout the Poor-Law Medical Service

[1] Proceedings of the Royal Society of Medicine, vol. x., No. 9, p. 129.

that some payment should be specially made for this work, as not appertaining to their official duties.

This matter is to be considered at a council meeting shortly to be held, and I should be greatly obliged if you could give me the following information. 1. In the opinion of the Local Government Board is the return referred to above comprised in the duties of Poor-law medical officers under Art. 205, Cons. Ord. July, 1847? 2. Would the Local Government Board be prepared to sanction a payment made by the guardians for this work?

Yours very obediently,
MAJOR GREENWOOD, M.D., LL.B., Hon. Sec.

Local Government Board, Whitehall, S.W.,
23rd November, 1911.

SIR,—I am directed by the Local Government Board to your letter of the 11th instant, with reference to the special return required by them in regard to paupers under treatment on the 4th November, 1911.

In reply I am directed to state that it appears to the Board that, under Article 205 (1) of the General Consolidated Order of the 24th July, 1847, it is the duty of a medical officer to furnish for the purpose of the return the requisite information respecting the case of any pauper who was under his care on the date in question.

I am to add that if in any particular case the guardians should be of opinion that an exceptional amount of work has been entailed upon the medical officer in connexion with the return, the Board would be prepared to consider an application from the guardians for their sanction to the payment of a reasonable gratuity.

I am, Sir, your obedient servant,
J. S. DAVY, Assistant Secretary.

Dr. Major Greenwood, Hon. Secretary,
Poor Law Medical Officers' Association,
34, Copthall-avenue, E.C.

VENESECTION IN THE LIGHT OF RECENT RESEARCH.

To the Editor of THE LANCET.

SIR,—In this year's Harveian Oration by Dr. C. Theodore Williams interesting reference is made to the treatment of consumption by blood-letting under the distinguished physicians of a bygone time, who employed it in their own empirical way. There is also evidence to show that this method was then looked upon as a panacea for all the ills, and self-medication, by resort to it in the barbers' shops, must have been an everyday occurrence in the large towns of Europe. The practice is in vogue, during the autumn and the spring, in a few Eastern countries at the present day, among semi-civilised Mahomedan peoples, who still cling to the old method of inoculation as a prophylactic against small-pox—needless to add, without the least aseptic precautions. The method probably originated with the old Arabian school of medicine B.C. But it is due to the highly instructive and important paper by Dr. R. F. Fox, entitled "Cases Illustrating the Use of Venesection," which appears in THE LANCET of Nov. 4th, that I feel prompted to add the following brief contribution.

The scientific significance of this method was, I believe, first elucidated in this country by Professor Dryer, of Oxford, at the Royal Army Medical College, Millbank, in November, 1907, by an elaborate lecture on the subject, at which I was a privileged listener. Professor Dryer, who is a pupil and colleague of Schröder of Copenhagen, drew special attention on that occasion to an "acme point" being reached, during successive proportionate bleedings of the inoculated rabbits, while their bodily resistance increased, and after further bleedings fell.

In Dr. Fox's excellent illustrations of both acute and chronic specific diseases it is acknowledged that no mere mechanical relief to the heart could explain the observed effects. Since Metchnikoff's epoch-making discovery of the phenomenon of phagocytosis as a mechanism of bodily defence, its relationship to the acquisition of immunity has been vaguely acknowledged and no more. There seems to be, therefore, a gap that requires linking up, with a view to the elucidation of these physiological phenomena. I venture to submit that this can only be achieved by increasing our little knowledge of the lymphatic systems of the body, about which next to nothing is known. The literature of this subject in English text-books is of the most meagre and fragmentary kind. One must needs turn to the elaborate works of such French authors as Poirrier, Cuneot, and Delamare, pupils of the great Sappey. The late Mr. Cecil H. Leaf's translation, entitled "The Lymphatics," is the most instructive English work of its kind. Since its publication in 1903, the subject has had a fascination for me, and I have taken notes.

I beg to submit the following suggestions for realisation: 1. Leucocytosis is a physiologically perpetual phenomenon on a vast scale, which is more noticeable after food is partaken of, and during extravascular infectious processes of the body. 2. Leucocytes are not the normal cellular constituents of the blood, but of the extra-vascular plasma. Their intrusion into the blood-stream is accidental, and in the venous blood they run risks of asphyxiation. 3. That while their relative proportion to the erythrocytes is 1 in 500 in the blood-stream itself, their actual proportion to erythrocytes in the body is nearer 5,000,000 to 1. 4. That phagocytosis is performed normally outside the blood-stream, where anti-bodies are only generated, and the lowering of blood pressure by venesection facilitates the infusion of these, by an aspiratory effect into the blood circulation.

I am, Sir, yours faithfully,
Wimpole-street, W., Nov. 15th, 1911. H. D. MCCULLOCH.

ELECTION OF DIRECT REPRESENTATIVES ON THE GENERAL MEDICAL COUNCIL.

To the Editor of THE LANCET.

SIR,—Kindly permit me through your valuable columns to thank the 3424 medical practitioners who recorded votes in my favour at the recent election. Especially are my thanks due to numerous personal friends in London and the provinces who voluntarily undertook the labour of forming committees and canvassing in their respective districts. I sincerely regret that the state of my health prevented me from effectively seconding their efforts by organising and attending meetings of the profession in London, Manchester, Liverpool, Leeds, and other large towns to discuss the objectionable National Insurance Bill and other medico-political questions of the day. Had the election campaign been carried out actively on the usual lines on behalf of my colleagues, Drs. Hawkyard and Lawrence, and myself, I venture to think that a considerable number of the 12,000 and more registered practitioners who did not take the trouble to fill up their voting papers would have voted solidly for us.

The events connected with the recent election, in my opinion, emphasise strongly the need of an early reform of the Medical Acts, especially in regard to Direct Representation on the General Medical Council.

I am, Sir, yours faithfully,
Callington, Cornwall, Nov. 15th, 1911. GEORGE BROWN.

A SPHYGMOGRAPHIC METHOD FOR THE ESTIMATION OF SYSTOLIC AND DIASTOLIC BLOOD PRESSURE.

To the Editor of THE LANCET.

SIR,—In Dr. Windle's note in your issue of Nov. 18th, he states that by the auscultatory method he takes as the reading of diastolic pressure the point at which the sound ceases to be heard on releasing air from the armlet bag. According to Dr. George Oliver and others, the point to take is that at which a distinct change in the intensity of the sound occurs, which is generally pronounced and limited to 1 or 2 mm. of the scale. The point at which the sound ceases to be heard is, I usually find, a very considerable number of mm. lower. In using Pachon's sphygmo-oscillometer, which has been recently described in various journals,[1] the point of definite decrease in the amplitude of oscillation on reducing air pressure is taken as corresponding to the point to which I refer, though on further reduction of pressure considerable oscillation still takes place. I have not, however, any practical experience of this instrument. It is still a debateable point as to what reading represents most truly the diastolic pressure. Having abandoned for some time the tactile method in favour of the auditory, I find the latter to give more precise readings, whatever their exact interpretation may be.—I am, Sir, yours faithfully,
Melton, Suffolk, Nov. 24th, 1911. STEPHEN G. LONGWORTH.

VETERINARY TRAINING AND THE PUBLIC HEALTH SERVICE.

To the Editor of THE LANCET.

SIR,—I should like to say a few words upon an annotation headed, "Veterinary Training and Public Health," which appeared in your columns recently. As one that has recently qualified at the London Veterinary College, and taken the post-graduate course at that institution, I could not help taking some of Dr. D. N. Knox's

[1] THE LANCET, Sept. 2nd, 1911, p. 680.

remarks as a slight to the veterinary profession, and I can only consider that he is ignorant of the methods of training employed at the Veterinary Colleges. The course of pathology and bacteriology at the London College, under Sir John McFadyean, is very thorough, and the students spend a considerable time in the laboratory. During the post-graduate course the men spend five hours a day in the laboratory for ten weeks, and I think that anyone having taken these two courses can reasonably consider himself capable to act as an official in a scientific laboratory. And I do not agree with Dr. Knox that at the present time, and for some time in the future, men would have to be chosen from the medical officers of health to fill these positions.

The final-year students and the men taking the post-graduate course attend the Islington cattle market regularly for the purpose of studying meat inspection, and lectures on this subject form part of the College curriculum. So that I think that the veterinary profession can justly claim to be the most suitable men, at least, for the inspection of meat. No other profession devotes its whole time and energy to the study of the diseases of the domestic animals.

I am, Sir, yours faithfully,

J. MALCOLM ARMFIELD, M.R.C.V.S.

Croydon, Nov. 14th, 1911.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Bristol Medical School: Annual Dinner.

THIS dinner was attended by over 100 past and present students of the Bristol Medical School. Mr. C. E. S. Flemming, of Bradford-on-Avon, occupied the chair, and Mr. Howard Marsh, professor of surgery in the University of Cambridge and Master of Downing College, was the guest of the evening. After the loyal toast, Professor Marsh's health was proposed by Mr. E. H. E. Stack; and Professor Marsh's reply included a proposal of the health of the University of Bristol. To this Professor E. Fawcett, Dean of the Medical School and professor of anatomy, replied for his own faculty, and Professor A. R. S. Kemp, professor of Greek, on behalf of the other faculties. The health of the students, past and present, was proposed by Dr. J. O. Symes, who spoke of the overloading of the curriculum and some of the evils consequent thereon, to which Dr. Cecil Clarke and Mr. C. C. Harrison replied. The health of the president was proposed in an admirable speech by his brother, Dr. A. L. Flemming.

Chancellorship of the University of Bristol.

It has been officially stated that the name of Lord Haldane will be submitted to the next meeting of the court in December for election to the Chancellorship of the University. It is universally agreed that no more suitable and honourable name could have been brought forward.

A Medical Mayor's Dilemma.

Dr. Charles J. Vlieland, the mayor of Exeter, who is one of the assistant medical officers of health of the city, recently placed his resignation of the latter office in the hands of the city council on the ground that his retaining a salaried appointment was incompatible with his holding the office of mayor. After some discussion, in which members of the council stated that it seemed most unfair to expect Dr. Vlieland permanently to resign the appointment and for the city to lose his valuable services, it was decided to accept the resignation for the year of office only. The matter was referred to the sanitary committee to make arrangements for the performance of his duties as assistant medical officer of health during the ensuing year.

Gloucestershire Royal Infirmary.

The annual meeting of the members of the Gloucestershire Royal Infirmary League was held on Nov. 15th, under the presidency of the chairman, Colonel Curtis Hayward. It was stated that during the past 12 months members of the league had collected £236, and that this sum had been handed over to the treasurer of the infirmary. Colonel Hayward said he was sorry to see that it was proposed to erect a memorial hospital to the late Sir Charles Dilke at Speech House, in the Forest of Dean. He hoped that the memorial would take the form of a convalescent home, as the original scheme would divert subscriptions from their own infirmary.

Acute Poliomyelitis in Devonshire.

The medical officer of health of Devon, Mr. G. Adkins, reports that since the outbreak of the disease last July, 129 cases of poliomyelitis have been reported, with 24 deaths. During the same period, four cases of cerebro-spinal fever have occurred.

The Didworthy Sanatorium for Consumptives.

On Nov. 4th, the mayor of Plymouth, in the presence of a large gathering, laid the foundation-stone of a new pavilion, to be added to the Didworthy Sanatorium for Consumption, at Brent, near Plymouth. This is a portion of the Plymouth memorial to the late King.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Association of School Medical Officers for Scotland.

A GENERAL meeting of this association was held in the Ophthalmic Institute, Glasgow, on Nov. 18th. Dr. E. T. Roberts, the president, occupied the chair, and 41 members were present. Seven new members were duly elected. Dr. H. Wright Thomson gave a demonstration of eye diseases in relation to school medical inspection. Cases of blepharitis marginalis, catarrhal and strumous ophthalmia, interstitial keratitis, trachoma, ophthalmia neonatorum, and myopia were shown. Dr. Thomson concluded his most instructive demonstration with a review of the methods of instruction at present employed in the education of the blind and partially blind. Dr. Walter F. Brown read a paper on "A Plea for Special Classes for Cases of High Myopia," in which he detailed the methods of teaching as carried on in these classes in London and elsewhere, and urged that such classes would be of great benefit in rural districts where access to institutions was difficult. On the proposal of Dr. Roberts votes of thanks were awarded Dr. Thomson and Dr. Brown. It was arranged to hold the next meeting of the association in Perth on Saturday, Jan. 20th, 1912.

Control of Phthisis in Glasgow.

The report just issued by the Local Government Board on the administrative control of tuberculosis in Glasgow is worthy of serious consideration, not only for its own sake and in relation to the specific recommendations—of which the chief is the vesting of all control in the public health authority instead of dividing control between that body and the parish councils—but because of its suggestive value as regards the best way of grappling with the whole problem involved. Two years ago, owing to the pressure on the available hospital and poorhouse accommodation, the Local Government Board instituted an investigation as to the whole control of tuberculosis in Glasgow, and three reports are the outcome of this investigation, and are given in a Blue-book just published. In the first Dr. F. Dittmar, medical inspector, summarises and illustrates the work of the Glasgow parish council, and also describes the sanitary and economic conditions of a series of patients on outdoor relief. In the second, Dr. Elizabeth M. McVail shows the work done in that section of Glasgow served by Govan combination poorhouse, and describes fully the clinical and economic conditions of 100 patients. In the third, Dr. T. F. Dewar deals with the administrative measures taken by the public health authority, and analyses 100 consecutive cases notified to the medical officer of health in order to illustrate the administrative difficulties and the methods whereby they may be solved. In his report Dr. Dewar draws attention to the fact that throughout the country generally considerable uncertainty prevails concerning the relation of the authorities entrusted with the administration of the Poor-law and the care of the public health respectively as regards the responsibility for the control and the eradication of tuberculosis. In Glasgow the problem is especially grave and acute for several reasons. The solution of the question is divided between two administrative departments, resulting in overlapping, want of continuity, and deficient coördination. There are yet other factors which make inquiry and consideration of the whole subject a matter of extreme urgency and difficulty. Under the existing Poor-law

in Scotland it is illegal to relieve the dependents, whether ill or healthy, of an able-bodied man. As a result, if a wife be tuberculous and the husband can only partially contribute towards her maintenance in hospital, she cannot be relieved. Again, as pointed out by the medical officer of health of the city, while the consumptive pauper may obtain accommodation and treatment in a Poor-law institution, there is no such provision for the patient just above him in the social scale, so that the improvident are better off than the provident. It is true that something much better than the law provides is frequently done, but all will admit that it is not a very healthy state of affairs when the law must be broken, or evaded, or ignored in the interest of humanity and common-sense. In Glasgow compulsory notification was adopted in 1910, and at present there are five sources of information—"private" notification from medical practitioners, "parochial" by the Poor-law medical officers; "public" notifications from hospitals, dispensaries, and other public medical institutions; "death-cards" (following the visit of a sanitary inspector to a house in which a death has occurred); and from the Poor-law hospitals. On receipt of notification, whatever its source, the patient's house is visited by a sanitary inspector, who fills up a schedule as to the home conditions, ascertains if the visits of the phthisis nurse would be acceptable, arranges for the washing and disinfection of clothes, and presents the patient with a leaflet of instructions. Four nurses are employed in the domiciliary visitation of patients' homes. In addition, five tuberculosis dispensaries have been established by the health authority throughout the city. These are intended to act as a "clearing house," and also to link up the various agencies into administrative association. Dr. Dewar makes the following suggestions:—

1. The whole duty and responsibility for the control of phthisis should be vested in the local authority (as apart from the relief of dependents rendered destitute by the incapacity of the wage-earner).
2. There should be such extension of the accommodation for cases of phthisis as will permit of (*a*) a period of educational isolation for early or hopeful cases; (*b*) isolation of all advanced cases prepared to accept it.
3. There should be such modification of the methods of disinfection as will imply the thorough cleaning of premises by the tenant or owner as advised by the sanitary authority.
4. Cases which have been notified should be kept under observation so long as they remain a menace to the public health.
5. Patients who are excreting tubercle bacilli should, under the powers conferred by the Public Health Act, be detained in hospital, if their houses or habits make domestic isolation impossible.
6. There should be close and regular supervision of all notified cases which usually reside in common lodging houses.
7. Suitable premises should be provided for the conduct of the work of the dispensaries, and that work extended by increase of medical and nursing staff.

Nov. 28th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Bicentenary of the School of Physic in Ireland.

A MOVEMENT is on foot to celebrate in suitable fashion the bicentenary of the School of Physic in Ireland, better known as the Medical School of Trinity College. Although there was a professor of physic and a *socius medicus* from the early times of the College, it was not until the second decade of the eighteenth century that anything like an organised school existed. Within a few years professorships and lectureships in anatomy, chemistry, botany, and physic were founded, the last-named from funds left by Sir Patrick Dun. It is proposed to hold the celebrations next June, and a provisional committee has been formed consisting of Professors James Little, Sir Charles Ball, W. H. Thompson, James Craig, A. Francis Dixon, Dr. A. C. O'Sullivan, and Dr. T. P. C. Kirkpatrick. A committee of graduates will shortly be formed, and those who are willing to become members are invited to send in their names. Meanwhile, the provisional committee is anxious to receive suggestions as to the conduct of the celebrations, and invites the loan of documents or other objects of interest which may illustrate the history of the school.

The Milk-supply Commission.

The Irish Milk-supply Commission, the appointment of which was announced recently, has commenced its sittings in Dublin Castle. Among the first witnesses examined were Sir Charles Cameron, medical officer of health of Dublin, Mr. A. Watson, chief veterinary inspector for Dublin, and a representative of the Local Government Board.

Town Planning Association.

A public meeting was held on Nov. 27th, under the presidency of Her Excellency the Countess of Aberdeen, to inaugurate a Housing and Town Planning Association of Ireland. The object of the association, as explained by a provisional committee, is to supply a permanent educative force on behalf of reform and regeneration, and to create in Ireland a body of sound public opinion which would eventuate in the uprise of beautiful and healthy towns, the amelioration of the hard lot of the workers, and indirectly in the decline of pauperism and crime.

The Government and Irish Schools.

At the monthly meeting of the Londonderry No. 1 School Attendance Committee on Nov. 22nd, the Ven. Archdeacon Colquhoun presiding, the Rev. Patrick O'Doherty proposed a resolution urging upon the Commissioners of National Education the necessity of providing a new school in the townland of Altahoney. The Rev. John Beckett, in seconding the resolution, said the Irish National Schools were a disgrace. He was strongly of opinion that Government should make the children its first care, for they were the only hope of the State. It is interesting to find the clergy of the various ecclesiastical bodies in Ireland taking steps to ventilate a matter to which medical men have so frequently called attention in Ireland.

Typhoid Fever Epidemic at Omagh Asylum.

At a meeting of Omagh rural council held on Nov. 25th the medical officer of health forwarded 77 notifications of cases of typhoid fever at Tyrone and Fermanagh Asylum. He again directed the council's attention to the necessity of the asylum authorities providing a tank for the proper treatment of the sewage before it reached the river which flowed through Omagh. The chairman replied that the cause of the outbreak had not yet been discovered, and suggested that the asylum authorities be asked if they had received a report on this matter from the expert they had employed, a course which was agreed to. It is to be hoped the Local Government Board will compel the authorities to take some action to prevent sewage from an institution full of typhoid fever patients to pass untreated into a river which subsequently passes through a county town until the cause of the outbreak is discovered.

Enteric Fever at Hillsborough, Co. Down.

At a meeting of the Hillsborough rural council held on Nov. 21st it was reported that the outbreak of enteric fever there was probably due to the pollution of the surface well used by the occupiers of eight houses, in four of which the disease had occurred. Suggestions were made by the Local Government Board Inspector (Dr. B. O'Brien), who pointed out that it was the duty of the sanitary authority to provide a pure water-supply, and that the wells should be properly protected and that pumps should be erected instead of the dip wells. A committee was appointed to investigate the matter.

Pomeroy Dispensary.

At a meeting of the Cookstown board of guardians, held on Nov. 25th, Mr. W. J. F. Mayne, M.B. Edin., was elected medical officer of the Pomeroy dispensary district at £80 per annum to begin with—that is, £10 less than formerly. Subsequently, at a meeting of the rural council, Dr. Mayne was appointed medical officer of health for the Pomeroy district at a salary of £20 per annum.

Nov. 28th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

The Canadian Death Toll in Four Years.

"WHAT we Pay for Hustle" is the title of an editorial article in the *Monetary Times*, Toronto, of recent date. In four years in Canada there have been killed by steam railways 2049 persons; by electric railways, 301; by industrial accidents, 5296; by fires, 1072; total, 8718. Those who have been injured by steam railways number 7344; by electric railways, 8296; by industrial accidents, 10,444;

by fires (estimated), 1908; total, 27,992. This looks as though Canada needs better laws for the protection of life.

St. John Ambulance for Quebec.

The general secretary of the St. John Ambulance Association has arrived in Montreal from Ottawa in connexion with the establishment of a provincial branch for this association in Quebec, with headquarters in Quebec. The Canadian branch, which was only recently organised, is at the present time giving instruction to more than 3000 people. The Canadian Pacific Railway, recognising the value of the movement, has established posts for instruction from coast to coast. After the branch is established in the province of Quebec five lectures on first aid will be given weekly by a Montreal physician. Lectures will also be given exclusively for women.

Small-pox in Quebec.

In spite of all the measures adopted by the Provincial Board of Health of Quebec small-pox is spreading in that province. The outbreak is active in the Lake St. John district, the North Shore of the St. Lawrence, Beauce County, L'Islet, Ottawa district, and St. Maurice County. In the latter county 20 cases were recorded during the first week in November, and the strictest quarantine measures have been adopted. Dr. Elzear Pelletier, secretary of the Quebec Board of Health, says that the greatest obstacle encountered by the board is the apathy of local municipal authorities, who are rather loath to enforce vaccination. He considers that opposition to general vaccination was the real cause of the actual outbreak. Country physicians are also too prone to diagnose mild cases of small-pox as chicken-pox.

McGill University as a Model for the English Royal Commission.

It is gratifying to Canadians that the structure and constitutional development of McGill University, as regards the relations of the University to practical trades and industries, is being carefully studied by a British Royal Commission. Before the Commission now sitting Principal Peterson gave some history of McGill in the last 15 years, which he summed up in the word "unification." He also cited the great reversion of feeling in connexion with the teaching of medicine in that institution. Whereas formerly to a large extent medical teaching was in the hands of practitioners, the medical men asserting that the proper teaching of medicine was the teaching of medical men by medical men, and the unification conception was depreciated, now the medical men of the school are satisfied that the university view of medical study is absolutely indispensable for the success of a well-conducted medical school. Referring to the sciences, Principal Peterson declared that the aim in Canada was to begin with the highest department of technical and scientific work. Every year from 80 to 90 men pass from McGill equipped with the science degree straight into well-remunerated positions of usefulness. The number of students from England is increasing year by year; and there are now some 50 or 60 English boys taking their education in the science branches alongside of Canadians. McGill has not yet rivalled Toronto University in granting a degree in domestic science.

Infant Mortality in Montreal.

Out of every 100 children born in the city of Montreal in the year 1909, when the last blue-book was issued on this subject, 29 died in the first year; and out of the total mortality of the people 54·92 per cent. was caused by the deaths of children under 5 years of age. In the month of July in the present year out of 1419 deaths 1033 were those of children under 5 years of age, giving 72·92 per cent. of that month's mortality. Out of 6297 deaths occurring in Montreal from Jan. 1st to July 31st, 1911, 3482 were those of children under 5 years of age. According to Professor N. H. Alcock, the newly appointed professor of physiology at McGill, succeeding the late Dr. Wesley Mills, one of the pressing needs of McGill University is an institute of physiology, which Professor Alcock considers could be provided for £5000 and maintained for £800 a year. He considers that the infantile death-rate in Montreal, through scientific precautions, could be materially lessened, as in Paris, where it has been reduced one-half.

Cancer in Ontario.

According to the report for 1909 of the Registrar-General of Ontario, which has just been issued, there were in that province 1597 cases of cancer resulting in death. The advance in cancer in the province is shown by the fact that in the year 1902 there were 1048 deaths from cancer; in 1903, 1156; 1904, 1253; 1905, 1224; 1906, 1411; 1907, 1329; 1908, 1348. In the county of York, in which Toronto, the chief city of Ontario and the second of Canada is situated, there were 308 deaths from cancer, of which 259 occurred in Toronto, but many go to the hospitals of the city to be operated on.

Deaths from Venereal Diseases in Ontario.

It is significant of the times that the Ontario Board of Health in its report takes cognisance to some extent of the deaths resulting from venereal diseases in that province. Under the head of syphilis and gonorrhœa the deaths are set at 25. Of these, 15 were found in children, 13 being in those under 1 year of age, and the remaining two under 2 years of age. Twenty-two of these cases occurred in the cities, 19 being in Toronto. The report considers this question one of vital importance, and advises systematic instruction in the schools about these diseases. Opinion is divided on this matter, but the opinion is growing that all venereal diseases should be under the direct surveillance of the medical health officer.

Deaths from Tuberculosis in Ontario.

In the year 1909 there were 2380 deaths from tuberculosis in Ontario. In 1870 the number was 886. Year by year these deaths increased until the year 1900, when they stood at 3484. Since that time there has been a decline. There were 131 less in 1909 than in 1908. The ratio per 1000 of the population is 1·06, whilst the percentage of deaths from tuberculosis, compared with the number (32,628) of deaths, is 7. The new building at Ste. Agathe is now in full operation and caring for 45 patients. The paid-up donation fund amounts to $85,949, but there is still a debt of $77,000 on the building. There was a deficit in the expenses for the year of $1,994.

Registration at the University of Toronto.

Over 3500 students have registered in all departments of the University of Toronto for the ensuing year. The arts number 1765; medicine, 512; education, 266; applied science, 780; household science, 143; forestry, 47. With "regular occasionals," dental and veterinary students, and teachers in the summer session, the year's total is brought up to 4144.

Academy of Medicine, Toronto.

The formal opening of the new building of the Academy of Medicine, Toronto, took place on Oct. 26th. The President, Dr. N. A. Powell, with Mrs. Powell, received a large number of members and their friends. Mr. Allan Hazen, a New York expert on water-supplies, delivered an address on the filtration plant about completed for Toronto. Dr. Powell's Presidential address went very fully into the hospital situation in Toronto. The Academy of Medicine will ask the Government to supply antityphoid vaccine to those going into lumber camps for the winter. Speaking on this resolution, Professor McPhedran considered it was more important for the Government to supply pure water.

Toronto's Filtration Plant.

The completion of Toronto's water filtration plant, which was begun two and a half years ago, is announced. The cost will be $1,250,000. It covers 17½ acres. It has 12 filters, each measuring 312 by 117 feet. The capacity of the filters is 50,000,000 gallons in 24 hours. The capacity of the pure-water reservoir is 8,000,000 gallons. The process is that of slow sand filtration. Each filter is lighted by 12 interior electric lights; its walls are 3 feet thick at the base and 20 inches thick at the top. Some time hence Filtration Plant Park will be one of the prettiest spots in the neighbourhood of Toronto Island.

Violent Deaths on the Increase in Toronto.

Toronto's list of violent deaths increases every year. The total number for the past official year reached 177, the number of drownings, as usual, heading the list with 29, one less than for the previous year. Carbolic acid poisoning comes next, claiming 18 victims. This would show that the law governing the sale of carbolic acid is not properly enforced. There were 17 deaths from street-car accidents; 13 steam-car accidents; 11 burned to death; and 7 automobile deaths. The victims of gas poisoning numbered 13,

as against 8 of the previous year. Five people shot themselves this year; last year, none. Three people hanged themselves.

Annual Meeting of the Laurentian Sanatorium.

The annual general meeting of the Laurentian Society was held recently in Montreal. Mr. D. Lorne McGibbon, the President, occupied the chair.

Nov. 7th.

Obituary.

WILLIAM WILFRID WEBB, M.D., C.M. ABERD., M.R.C.S. ENG., F.S.A.,

LATE MAJOR, INDIAN MEDICAL SERVICE.

Dr. Wilfrid Webb was a son of Dr. F. C. Webb, physician to the Great Northern Hospital and editor of the *Medical Times and Gazette*. He was born in 1857, and was educated at King's College School, at Charing Cross Hospital, and at the University of Aberdeen. He became L.S.A. in 1878, M.R.C.S. in 1880, and in April, 1881, he graduated M.B., C.M., at Aberdeen, with highest academical honours, being the only man in his year to gain this distinction. He graduated M.D. in 1894. He held the following appointments in London before entering the Indian Medical Service: assistant demonstrator of anatomy and demonstrator of physiology at Charing Cross Hospital School, house physician at the Great Northern Hospital, and medical registrar at Charing Cross Hospital. In the spring of 1882 he suffered severely from rheumatic fever, and by the advice of his friends he gave up his intention to practise as a physician in London. In 1882 he obtained the second place in the open competition for commissions in the Indian Medical Service. At Netley he was awarded the gold medal for military medicine and the Fayrer prize in pathology. Proceeding to India, he served in the following regiments: 14th Sikhs, 2nd Regiment of Central India Horse, 29th Punjab Infantry and Meywar Bhil Corps. In the July of 1886 he was seconded for service in the political department under the Indian Foreign Service, being sent as residency surgeon to the court of H.H. the Maharanah of Udaipur, and thence he was in due course transferred to Bikanir. At Bikanir, as at Udaipur, he not only had charge of the Government medical work, but he was also superintendent of all the hospitals, dispensaries, and jails in these States and head of the vaccination department. In 1888 he acted as guardian to H.H. Ganga Singh, and he also held charge of the Bikanir Political Agency. His career in India was brought to a close by another attack of rheumatic fever, and in 1894 he was placed on permanent half-pay. In 1893 he became secretary of the Army Medical School and curator of the Museum at Netley. There he remained until the abolition of the Army Medical School, when his connexion with the service was finally severed. While at Netley he carried on a considerable private practice, and took an active interest in local affairs. In 1899 in consequence of the issue of the Royal Warrant, he was ordered to assume the title of captain, and in 1900 he was promoted to the temporary rank of major. During his life he did much useful literary work; he was for about 15 years a constant contributor to THE LANCET, and for many years he contributed the article on the Public Services to our Students' Number. He also published a book on the Indian Medical Service in 1890, and a work on "The Currencies of the Hindu States of Rajputana," illustrated by himself. He took great interest in biographical, genealogical, and heraldic work, and contributed many articles to "The Dictionary of National Biography." On the abolition of the Army Medical School he went to reside at Berkhamsted. Subsequently he moved to Exeter, where he died on Nov. 18th.

Dr. Wilfrid Webb will be greatly regretted by all who knew him. The above brief enumeration of the facts of his life shows that he was a highly gifted man, whose promising career was terribly prejudiced by ill-health.

WILLIAM MILLINGTON, M.D. EDIN., M.R.C.P. LOND.,

CONSULTING PHYSICIAN, WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.

ANOTHER link with the past has been severed by the death, on Nov. 5th, of Dr. William Millington, of the Clevelands, Wolverhampton, at the advanced age of 90 years.

Born at Oldbury in 1821, he began his professional studies at Guy's Hospital, London, where he came under the teaching of Aston Key, Bransby Cooper, Cock, Hilton, and Poland. He afterwards proceeded to Dublin and to Edinburgh, where he was clinical assistant to Dr. Robert Christison and Dr. Allison. He tied with the late Sir John Burdon Sanderson for one of the University distinctions. In 1851 he obtained the graduation gold medal for the thesis on the Pathology of Pus in the Blood. Many of the observations upon which this essay was based were the outcome of his studies under Sir James Y. Simpson, who wrote of his pupil, "He is sure to acquire the very first rank in his profession in whatever part of the world he may settle, for I have seldom seen professional zeal and earnestness more thoroughly combined with extensive professional abilities and information." Until the last year of his life he continued to take the same keen interest in pathological and clinical details which had characterised him as a younger man.

Having already enjoyed extensive opportunities for clinical study, he spent the summer of 1843 in Paris, where he attended the hospital practice and teaching of Roux, Lisfranc, and Velpeau. He became a Member of the Royal College of Physicians of London in 1859. In 1852 he was elected honorary physician to the South Staffordshire and Wolverhampton Hospital, with which institution he was thus connected for 60 years. For many years he was indefatigable in his work there, where an enormous number of patients attended under him, and where his reputation added greatly to that of the hospital. At the same time he had a large and extended practice, both private and consulting. He will chiefly be remembered by many of his patients as a pioneer in the open-air treatment of consumption, of which he was always a strenuous advocate. On his retirement from the staff of the hospital in 1885 he was elected consulting physician. He was largely instrumental in founding the Wolverhampton Eye Infirmary and was a member of the managing committee.

Dr. Millington was one of the original members of the Staffordshire county council and did valuable work, especially on the health committee of that body. He was a liberal supporter of many charitable and religious institutions.

The deceased leaves a widow, who is a sister of Sir Robert Ball, the professor of astronomy at Cambridge, and of Sir Charles Ball, the Regius professor of surgery at the University of Dublin, both of whom attended his funeral.

WILLIAM HENRY WEBB, M.D. DURH., L.R.C.P. LOND., M.R.C.S. ENG., L.S.A.,

SURGEON-LIEUTENANT-COLONEL 2ND BATTALION DEVON REGIMENT (T.F.), V.D.; MEDICAL OFFICER OF HEALTH OF KINGSBRIDGE (DEVON) URBAN AND RURAL DISTRICTS.

Dr. W. H. Webb died at Thurlestone, Devon, on Nov. 14th, in his fifty-ninth year. The deceased, who received his medical education at St. Bartholomew's Hospital, London, qualified M.R.C.S. Eng. and L.S.A. in 1876, ten years later he obtained the L.R.C.P. Lond., and graduated M.D. of Durham in 1893. Dr. Webb joined the late Dr. Cornish in partnership at Kingsbridge about 30 years ago, and on the retirement of the latter a few years later succeeded to the practice. He was highly respected and esteemed in Kingsbridge and the district, and had a very extensive practice. He was medical officer of health of the Kingsbridge urban and rural districts, honorary surgeon to the Kingsbridge Cottage Hospital, medical officer and public vaccinator for the third, fifth, and tenth districts of the Kingsbridge Union, and was also certifying factory surgeon for the district. He took a great interest in the Volunteer movement, and was Surgeon-Lieutenant-Colonel of the 2nd Battalion Devon Regiment (T.F.), V.D. He was a keen worker also in all local matters connected with Kingsbridge, and served on several of the public bodies connected with the town.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Bernhard Fraenkel, formerly honorary professor of laryngology in the University of Berlin, aged 75. His early professional life was spent in general practice in Berlin, and as a military surgeon during the wars of 1864, 1866, and 1870. Later he held various hospital appointments in Berlin and lectured on children's diseases. He then established a private dispensary for throat and nose cases, and obtained so much reputation for his scientific work in that field that the university took over the dispensary and made it a university clinic, Dr. Fraenkel being appointed

professor. This was the first university laryngological clinic established in Prussia. His publications are very numerous and include articles on throat and nose diseases in Ziemssen's Handbook and Eulenburg's Encyclopædia. He also edited the *Zeitschrift für Praktische Medizin* and the *Archiv für Laryngologie*. In addition to his purely scientific work he took a great part in the conduct of medical societies and was much esteemed in professional and non-professional circles, where he will be greatly missed.—Dr. Vincenz Fukala, of Vienna, whose views on the correction of myopia by operative measures attracted attention some years ago. His age was 64.—Dr. Louis Harvey Jones, formerly professor of forensic medicine in the Atlanta College of Physicians and Surgeons.—Dr. Hermann Kiefer, formerly professor of medicine in the Ann Arbor University, Michigan.—Dr. Henry Merriman, formerly lecturer on gynæcology in the Rush Medical College, Chicago.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

—o—

TUESDAY, NOV. 28TH.

THE General Council of Medical Education and Registration commenced its winter session at its offices, 299, Oxford-street, W., to-day. Sir DONALD MACALISTER, the President, was in the chair.

New Member.

Mr. Rutherford John Pye-Smith took his seat as representative of the University of Sheffield. He was introduced by Dr. Caton.

The President's Address.

The President, Sir DONALD MACALISTER, then delivered his address. He said: We miss to-day, with deep regret, the familiar and ever-helpful presence of our general registrar, Mr. H. E. Allen. The news of his sudden death on July 10th brought a sense of personal loss to every member of the Council. For 33 years he had been associated with its work, and had performed the important duties assigned to him with assiduity and skill. Of those who constituted the Council when he entered its service not one is now with us, and only four remain of those who took part in his first appointment as general registrar. His great experience in all that related to the Council's business, his fidelity in carrying out its decisions, and his unsparing efforts to promote the efficiency of its administration, were constantly and gratefully recognised by successive Presidents, treasurers, and other members of the Council. His courteous bearing and his readiness to be of service impressed all who sought his aid, whether officially or privately. The spontaneous tributes paid to his memory by those within and without the Council whom he had thus assisted and befriended testify to the warm regard in which he was held. The Executive Committee, which naturally had special opportunities of estimating his character and abilities, has placed on the minutes an expression of its appreciation which the Council as a whole will doubtless endorse with sympathy.

In accordance with the Standing Orders the Executive Committee met in July and appointed the Assistant Secretary, Mr. Norman Carew King, to perform temporarily the duties of Registrar. With the loyal help of the other members of the staff Mr. King, as Acting Registrar, has since carried on the regular operations of the office. To these has been added the onerous and responsible work connected with the recent general election of Direct Representatives, undertaken on behalf of the English Branch Council. As President I have paid frequent visits to the office during the recess, and I have assured myself, as I am now pleased to assure the Council, that its administrative business has been conducted with great efficiency and economy under Mr. King's direction, and that its interests have suffered no detriment during the vacancy in the registrarship.

Certain changes in the membership of the Council have been intimated as actual or imminent. Dr. Cocking, the first member appointed by the University of Sheffield, whose ill-health prevented him, to our regret, from attending last session, has resigned his seat. In his place the University sends Mr. R. J. Pye-Smith, its Professor of Surgery. He bears a name that is honourably associated with the profession of medicine, and in particular with the rise and progress of the Sheffield Medical School. Dr. Finlay is about to resign the Regius chair of medicine in the University of Aberdeen and will retire from the Council next month. Happily, he will continue during the present session to afford us the benefit of his sound and sober counsel, in relation especially to the work of the Penal Cases and Examination Committees, to which during the past ten years he has rendered much good service. It is announced that his successor is Professor Theodore Cash, F.R.S., whose eminence as an investigator in the domain of rational therapeutics will ensure him a welcome. The election of a representative by the registered practitioners of Scotland has resulted in the return of Dr. Norman Walker unopposed. This notable token of approval and confidence on the part of his professional brethren in Scotland will give much satisfaction to his colleagues on the Council. In England Dr. Langley Browne and Dr. Latimer have been re-elected, by large majorities, for a further term of five years. The Council is to be congratulated on thus retaining the services of two members who have in the past so ably contributed to its practical efficiency. In pursuance of a recent Order in Council, an additional representative was elected at the same time, to hold office from the beginning of January. The new member is Dr. T. J. Verrall, and the election shows that he holds a high place in the favour of his fellow practitioners. He has taken an active part in medical organisation and is conversant with the public questions which at present engage professional attention. His experience will enable him to contribute a valuable element to our discussions.

Before turning to topics other than personal, let me mention the passing of one of the most eminent of our former members, the late Sir Samuel Wilks. He sat with us as the representative of the University of London for nine years, during which he was at the height of his fame as a scientific physician. His strong individuality, his sententious wisdom, and his downright sincerity of purpose, made an abiding impression on those who then were privileged to work with him.

The progress through Parliament of the National Insurance Bill has been watched by your committee with close attention, and occasionally with some perplexity. The proposals for its amendment, which you adopted at the last session, were duly communicated to the Government through the Lord President; and they were also advocated at personal interviews with the Chancellor of the Exchequer and other officers of the Treasury. The correspondence with the Chancellor which ensued has been made public at his request, and is in your possession. The Chancellor indicated his personal agreement with most of the Council's recommendations, and promised that they should have his favourable consideration when the Bill came to be amended in Committee of the House of Commons. Copies of the Bill, as amended in Committee, have now been placed before you, in order that you may judge of the extent to which effect has been given to your suggestions. The committee in charge of the subject will report on it during the present session of the Council, but in the meantime it may be convenient if I indicate in a few words the position which appears to have been reached.

It is now provided that of the Insurance Commissioners for England "one at least shall be a duly qualified medical practitioner who has had personal experience of general practice." The Advisory Committee, appointed for the purpose of giving the Insurance Commissioners advice and assistance in connexion with the making and altering of regulations, is by law to include duly qualified medical practitioners. The Local Health Committee (otherwise called the Insurance Committee) of a district may now consist of from 40 to 80 members. Of these, two are to be elected by the medical practitioners of the district, and at least one other member is to be a practitioner appointed by the Insurance Commissioners. It was pointed out by your committee that in the Bill as originally framed it might happen that not more than two practitioners were appointed on a Local Committee of 22. It will be observed that under the new provisions it is possible that a Local Committee of 80 may not include more that three medical practitioners. The Insurance Commissioners have power to appoint a larger number if they think fit, but they are not obliged to do so. The Council will have to consider whether the minimum

proportion prescribed by the Bill can be described as adequate.

A very satisfactory change in the Bill has been made in respect of the administration of "medical benefits." It is now provided that "medical and sanatorium benefits shall in all cases be administered by and through Local Health Committees." If this provision stood alone it would fully meet the request which was strongly urged by the Council—namely, that the administration of medical benefits by "approved societies" should be eliminated from the scheme of the Bill. But a clause, subsequently introduced, modifies to some extent the universal application of the principle thus laid down. The clause referred to admits "medical attendance and treatment," supplied under an existing system or organisation, to recognition and subsidy as "medical benefit" under the general scheme. This arrangement may prove to have a far-reaching application. As it appears likely to perpetuate the undesirable features of systems of "medical aid," already pronounced by the Council to be detrimental to professional efficiency, and therefore to the public welfare, it should not receive any sanction from us.

The regulations respecting "medical benefit" to be made by the Local Committee, with the approval of the Insurance Commissioners, are to be so framed as to provide for the establishment of a list of practitioners willing to act under the scheme, for the choice by an insured patient of the practitioner who is to attend him, and for the supply of medicines and appliances by properly qualified pharmacists. The importance of these points, which seem to have been overlooked in the original Bill, was pressed upon the Government by your committee. It is satisfactory to find that they have received due attention in the amended Bill. But it must be kept in mind that these and many other questions, on whose satisfactory solution the successful working of the scheme will depend, are to a large extent transferred from the domain of statutory enactment to that of local administrative regulation. For this reason it is of the highest importance that the various authorities concerned, both in framing and in carrying out the local regulations, should have ample facilities for obtaining counsel and assistance from medical practitioners of experience.

On the important question of the hospital treatment of insured persons, some steps have been taken to amend the Bill in the sense desired by the Council. There is still, however, much ground for the fear that the stability of many of the clinical hospitals will be endangered by the operation of the scheme, even in its present form. The efficiency of these institutions, in which medical students receive their practical training in the diagnosis and treatment of disease, is a matter of deep concern to this Council. It is our simple duty, in the public interest, to continue to urge upon the Government the importance of ensuring that their efficiency shall not be impaired.

With reference to the somewhat obscure subject of "maternity benefit," which is to be administered either by an "approved society" or by the Local Committee, it is now arranged that the mother shall herself select the medical practitioner or midwife who is to attend her. I have been informed that a further amendment is contemplated whereby the fee of a practitioner, who is called to attend a case initially under the charge of a midwife, will be chargeable on the funds of the body administering the "maternity benefit." This amendment, if adopted, may help to remove a defect which has seriously marred the working of the Midwives Act. It remains to add that bodies of Insurance Commissioners, distinct from the Commissioners for England, are to be established for Scotland, Ireland, and Wales respectively. It is not expressly provided that these bodies, or the Advisory Committees which will presumably be appointed to assist them, shall include any medical practitioners. This may be an oversight, but it should be made good before the Bill passes into law. In the case of Ireland "medical benefit" is for the present excluded from the purview of the general scheme. Whether the members of the Branch Council for Ireland will view this exclusion with apprehension or with relief I am not in a position to state. In a sense, however, it disposes for the present of the point raised by the Council—namely, that the Irish Poor-law Medical Service should be kept separate from the medical service of the insured part of the population.

The attention of Parliament has been so completely preoccupied since we last met that no steps have yet been taken to bring before it proposals relating to the administration of anæsthetics, the restriction of unqualified practice, or the registration of diplomas in tropical medicine. As a result of recent judicial decisions, it has become notorious that the law, with regard to the assumption by unqualified persons of misleading designations in dentistry, is seriously defective, and ought in the interest of the public to be amended forthwith. The inquiries I have made on behalf of the Council as to the prospects of legislation on any of these matters in the coming session of Parliament have yielded little ground for hopeful expectation. The Council can only continue to press on the attention of the Government departments concerned the gravity of the existing conditions and the necessity of providing a remedy.

The Pharmacopœia Committee has undertaken the duty of preparing a revised text of the British Pharmacopœia with a view to a new issue. It has appointed as editors Professor Tirard, of King's College, London, and Professor Greenish, of the Pharmaceutical Society of Great Britain. Each of these gentlemen has taken an important part in the preliminary inquiries, which have been for some years in progress under the direction of the Pharmacopœia Committee itself, and of the Committee of Reference in Pharmacy nominated by the Pharmaceutical Societies of Great Britain and of Ireland. They are at present engaged in arranging the abundant materials bearing on the subject of revision which have been accumulated by the committee since the last issue of the Pharmacopœia and its addendum, and they will therefrom prepare a first draft of successive sections of the new issue for the consideration of the committee. The committee will from time to time report as to the progress made; but some considerable interval must elapse before the complete work is ready for submission to the Council.

The inspection of the various qualifying examinations in dentistry and dental surgery has been carried out during the past year by Mr. A. S. Underwood. His official reports, with the observations thereon made by the qualifying bodies, and a report on the results of the cycle of inspections by the Dental Education and Examination Committee, will probably be placed before you at the present session. The memoranda received from the several universities and colleges on the subject of public health diplomas, with special reference to recent proposals for altering the educational and other conditions under which these are now conferred, will be communicated by the Public Health Committee. The Council will thus have at its disposal the materials necessary for a considered judgment on the proposals in question.

So far as I can estimate from the documents before me, the other matters which fall to be dealt with on this occasion, though important in themselves, are not likely to require a prolonged sitting of the Council.

On the motion of Dr. LITTLE the President was thanked for his address.

Commissions in the Services.

On the motion of Sir DAVID MCVAIL, the following yearly tables for 1911 were received: (*a*) Table showing results of competition held in May, 1911, for vacancies in the Naval Medical Service; (*b*) table showing results of competition held in July, 1911, for commissions in the Indian Medical Service.

It was also agreed, on the motion of Sir DAVID MCVAIL,

That the thanks of the Council be conveyed to the Director-General of the Medical Department of the Royal Navy and the Under-Secretary of State for India respectively, for the returns which they have again furnished to the Council, with the request that such returns may in the future continue to be furnished to the General Medical Council.

Apothecaries Society of London.

On the motion of Mr. NORTON, Mr. Vincent Warren Low, F.R.C.S., was appointed Assistant Examiner in Surgery to the Apothecaries Society of London in the place of Mr. Stansfield Collier, who retired on account of illness.

The New General Registrar.

The Council, sitting *in camerâ*, appointed Mr. Norman Carew King to the office of General Registrar, which was rendered vacant by the death of Mr. H. E. Allen.

Penal Cases.

The Council took up the consideration of penal cases. The most important of these was that of Mr. James Robertson Wallace, who had been required by the Council at their last session to produce evidence at the present session that his professional conduct had been satisfactory. Mr. Wallace explained his position at the Health Institute connected with

the name of Mr. Sandow, and the Council decided to postpone judgment on the case until next session, requiring of Mr. Wallace the testimony of medical practitioners or other persons of position as to his practice and conduct in the interval. Mr. C. E. Trimble was informed by the President that owing to his conformity to professional standards since the summer session his name would remain on the Register.

Restorations to Dentists Register.

After deliberation *in camerâ* the PRESIDENT announced that the Registrar had been directed to restore to the Dentists Register the names of Walter Clifford, Ruby Edmund Clifford, Isidore Clifford, and Stanley Clifford.

WEDNESDAY, NOV. 29TH.

The whole of the sitting was occupied with the consideration of penal cases.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—E. G. Brisco-Owen (Section II.), Cardiff and Royal Free Hospital; B. W. Brown (Sections I. and II.), Westminster Hospital; and C. C. Messiter (Sections I. and II.), St. Bartholomew's Hospital).
Medicine.—F. C. Shone (Section I.), University College Hospital; and W. H. Vincent (Sections I. and II.), St. Mary's Hospital.
Forensic Medicine.—B. W. Brown, Westminster Hospital; and L. K. Edmeades, Guy's Hospital.
Midwifery.—B. W. Brown, Westminster Hospital; and A. J. Tozer, St. Mary's Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: E. G. Brisco-Owen and C. C. Messiter.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berne:* Dr. Guggisberg, *privat-docent* of midwifery and gynæcology, has been promoted to the chair vacated by Dr. Kehrer, who is going to Dresden.—*Breslau:* Dr. Karl Alexander, whose specialty is urinary surgery, has been granted the title of Professor.—*Königsberg:* Dr. Franz Unterberger has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Santiago (Chile):* Dr. Westenhoeffer, who has for some years been engaged in teaching pathological anatomy and establishing a pathological institute on German lines, has recently returned to Berlin, where he was formerly Virchow's assistant. Before leaving he was honoured by a great demonstration of Chilian students, amongst whom he was very popular.—*Tübingen:* The well-known gynæcologist Dr. August Meyer has been awarded a University prize of £500 for his researches.

THE ROYAL DENTAL HOSPITAL OF LONDON.—The annual dinner of the staff and past and present students of the Royal Dental Hospital of London was held at the Hotel Metropole on Nov. 24th, Mr. Walter Harrison occupying the chair. The chairman, in proposing the toast of "The Past and Present Students of the Royal Dental Hospital and the Dental School," said he very much appreciated the honour they had done him in asking him to be the representative old student to preside on that occasion. It was always a joy to meet old colleagues, and their annual gathering was a source of encouragement to the present students. He drew an interesting comparison between the way educational work was done in his student days and the progressive methods of the present time. As a teaching institution he was sure the Royal Dental Hospital took the lead for efficiency. He thought the teaching of chemistry and physics within the walls of the hospital a step in the right direction. He suggested that an annual oration should be instituted on these occasions. Mr. G. Northcroft replied in appropriate terms on behalf of the past students, and Mr. E. B. Armitage in a quite neat speech undertook the same duty for the present students, referring in eulogistic terms to the hospital staff and the teachers in the school. The Dean also responded to this toast, and referred to the success of the popular lectures which had been instituted, and to the research work, principally in connexion with the teeth of children, which had been carried out in the school. The toast of "The Visitors" was proposed by Mr. R. McKay, to which Dr. W. Hunter replied. The toast of "The Chairman" was proposed by Mr. C. Robbins. During the evening an excellent and enjoyable programme of music was gone through.

THE NATIONAL LEAGUE FOR PHYSICAL EDUCATION AND IMPROVEMENT.—The sixth annual general meeting of this league will be held at the Mansion House on Friday next, Dec. 8th, at 3.30 P.M., the Lord Mayor of London in the chair.

NAVAL MEDICAL DINNER.—We are asked to state that this dinner had to be deferred on account of the movements of the various divisions of the Home Fleet, but that Dec. 19th has now been fixed upon and officers concerned will receive detailed notices. Communications may be made to Deputy Surgeon-General J. Lloyd Thomas, Dinmor, Penmon, Beaumaris.

ACCIDENT TO PROFESSOR NEISSER, OF BRESLAU.—Dr. Neisser, whose name is well known in England, has had the misfortune to fracture his thigh. The accident occurred while he was inspecting some buildings to be used in a special exhibition of what we should call lock hospital arrangements. According to the latest intelligence he is progressing favourably.

UNIVERSITY EXTENSION GUILD (UNIVERSITY OF LONDON).—Mr. D'Arcy Power will deliver a lecture at the University of London on Friday evening next, Dec. 8th, taking as his subject the Evolution of the Surgeon in London. The lecture will commence at 8.15, and tickets of admission, price 2*s.* 6*d.*, can be obtained on application by post to the honorary secretaries of the guild, care of the Registrar, University Extension Board, University of London, S.W. Members of the guild will be admitted free.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on Nov. 17th, Dr. F. de Havilland Hall being in the chair. The records of the society are still very satisfactory, showing a good increase in the number of new entrants and a large addition to the funds, which now amount to just upon a quarter of a million sterling. The increase in the number of members is made more gratifying by the fact that the society has no agents, pays no commission for the introduction of new business, and spends almost nothing on advertisement. Over £180,000 have been disbursed by the society in claims, and in this way the advantages of membership are brought to the notice of the medical profession. Prospectuses and all further particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.—A council meeting of this association was held at 34, Copthall-avenue, E.C., on Nov. 21st. Surgeon-General G. J. H. Evatt, in the absence of Mr. D. B. Balding, chairman of council, presided. It was reported that the dispute between the Islington guardians and the local profession had been settled, and the "warning notice" withdrawn. In the dispute between the Shoreditch guardians and the local profession the honorary secretary, Dr. Major Greenwood, pointed out that the effect of local professional action had been to raise the salary of the district from £115 to £150 a year. No local practitioner had come forward, but the appointment had been given to the late assistant of one of them. Certain correspondence between the honorary secretary, Mr. E. G. D. Pineo, of Axbridge, and the clerk to the Axbridge guardians was laid before the council. Mr. Pineo had attended under a medical order a pauper who had died leaving a considerable estate, and he claimed to be paid extra out of this estate. The next-of-kin who inherited the money did not dispute the claim, but letters had passed between the clerk to the Axbridge guardians and Dr. Major Greenwood as to the legal position of the guardians in the matter. The council expressed its satisfaction that Mr. Pineo had recovered his charges, and thought that the legal opinion of the honorary secretary was probably correct, though the clerk did not accept it. The council then considered the recent circular of the Local Government Board respecting statistical information with respect to all paupers under treatment on Nov. 4th last. A letter was read from Mr. W. C. Milward, of Cardiff, enclosing another from the clerk to the Cardiff guardians, which very clearly denoted the amount of extra work thereby thrown on the medical officers if the requirements of the Local Government Board were to be properly carried out. Dr. Greenwood wished to know if any action was

to be taken by the association. He had written to the Local Government Board on the subject, but had as yet received no answer. He thought personally that such duties did not come under Article 205 (1) of the General Consolidated Order, July 24th, 1847, and that some extra payment ought to be made, but it was difficult to say what action could be taken at the present time. The council was strongly of opinion that extra payment should be made for this work, but did not think the time opportune to press the matter. It was resolved to wait till an answer had been received from the Local Government Board to a letter on the subject from the honorary secretary of the association (see p. 1589).

SOCIETY OF APOTHECARIES: LORD MAYOR'S DAY DINNER.—A distinguished company dined with the Society of Apothecaries on Nov. 29th in the ancient hall of the society. The Lord Mayor, Sir Thomas Crosby, M.D., who is this year's Master, presided, and he received many congratulations upon the great honour which the City of London has conferred upon him and upon the vigour and health which he enjoys at the advanced age of 81. He was supported by the President of the Royal College of Physicians of London (Sir Thomas Barlow), the President of the Royal College of Surgeons of England (Mr. Rickman Godlee), the Sheriffs of London, Dr. Norman Moore (representing the President of the General Medical Council), Sir Francis Champneys, Sir James Goodhart, Dr. J. Mitchell Bruce, Sir David McVail, Sir John Moore, Sir Shirley Murphy, Mr. G. H. Makins, and other leading members of the medical profession.

THE NATIONAL SANATORIUM, BENENDEN: A VISIT BY PRINCESS CHRISTIAN.—Her Royal Highness Princess Christian paid a surprise visit to Benenden Sanatorium on Nov. 25th. Her Royal Highness, who is the president of the National Sanatorium Association, was accompanied by Lord Camden, the Lord Lieutenant of the county of Kent, Lady Camden, the Hon. Mrs. William West, and Major Martin. The party visited the wards, administration buildings, and dining and recreation halls, as well as the gardens where the patients are under treatment by a system of graduated work. Patients were seen employed at all the various gardening operations and in carpentry in the open-air workshops of the establishment. Those patients nearing the completion of their treatment were seen performing tasks requiring heavy muscular exertion, whilst those in the earlier stages of treatment were occupied in such light tasks as wood-chopping and weeding. Princess Christian in leaving expressed her keen interest in the work being done by the sanatorium and the excellent results which were being obtained. Her Royal Highness was received by the chairman of the institution, Mr. C. H. Garland, and the honorary advisory physician, Dr. T. D. Lister (who were present on a visit of inspection); the medical superintendent, Dr. J. D. Macfie; Dr. G. M. Mayberry, assistant medical superintendent; and the secretary, Mr. Henry Seagrave.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The National Insurance Bill.

THE names of the Commissioners under the National Insurance Bill, with the exception of that of the medical Commissioner, have been announced by the Chancellor of the Exchequer. The chairman will be Sir ROBERT MORANT, the permanent secretary of the Board of Education. The others will be Mr. JOHN BRADBURY, C.B., principal clerk to the Finance Department of the Treasury; Mr. D. J. SHACKLETON, labour adviser to the Home Office; Mr. J. LISTER STEAD, secretary to one of the largest friendly societies in the kingdom; and Miss MONA WILSON. Mr. J. D. STUART SIM, the Chief Registrar of the Friendly Societies, will be an *ex-officio* member of the Commission, to which Mr. W. J. BRAITHWAITE will be secretary. Mr. LLOYD GEORGE is not yet in a position to announce the name of the medical member of the Commission.

The House of Commons commenced consideration of the National Insurance Bill on report on Tuesday, Nov. 28th. New clauses were first dealt with. One was adopted on the motion of the Chancellor of the Exchequer which has for its purpose to permit of the variation of benefits in certain cases.

Further Concessions to Medical Representations.

As the result of deputations to the Chancellor of the Exchequer made during the week from the British Medical Association Mr. LLOYD GEORGE has placed on the paper a series of amendments, which have been summarised as follows in a *communiqué* to the press:—

An increased representation of doctors on the Health Committees to be appointed by the county councils.

Insured persons, although receiving benefits through institutions existing at the time the Bill passes, are to have the option of exercising their free choice of medical attendants.

Persons who are aged and infirm and cannot be insured, but who are present members of a society which has become an approved society, are to receive medical attendance and treatment on the same terms as those arranged with respect to insured persons.

Health Committees to have power to appoint not only district committees but sub-committees, a coöpted element being admitted to the latter.

Medical committees are empowered to arrange for district medical committees.

A Conciliation Board will be set up to settle medical disputes.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 22ND.

Scottish Insurance Commissioners.

IN answer to Mr. BARNES, Mr. MCKINNON WOOD (Secretary to the Treasury) stated that a woman would be appointed as a member of the Scottish Insurance Commissioners.

Foreign Milk and Contagious Disease.

Mr. STANIER asked the President of the Local Government Board whether the milk imported from foreign countries (where it was known contagious diseases existed) was examined bacterially and otherwise to see there was no contamination and that the milk was pure and free from disease.—Mr. BURNS said in reply: Samples of fresh milk imported from abroad continue to be taken by my officers for bacteriological examination in regard to tubercle and examination as to general cleanliness of the milk. During the past autumn 28 samples of fresh milk have been taken from consignments arriving from France and Holland, which have been the only sources of this supply. No tubercle has been found in the 13 samples so far reported upon, and no exception can be taken to the milk on the ground of its general cleanliness.

Mr. STANIER: Is it examined before it is allowed to be retailed in this country?—Mr. BURNS: Yes; and it is subject to examination by local authorities.

Feeding London School Children.

Sir CLEMENT KINLOCH-COOKE asked the President of the Board of Education whether he was aware that the number of meals provided out of the rates in 1910 for children in London County Council schools was 9,100,000, showing an increase of 1,800,000 over the figures for 1909; and whether he could explain the cause of the increase.—Mr. J. A. PEASE replied: The facts are as stated in the first part of the question. It is understood that the increase may be attributed to the more complete development of the system of care committees and to the greater attention paid by them to the question of malnutrition as affecting the education of children in the elementary schools. Meals were provided in 165 more schools in London during the year 1909-10 than in the preceding year.

Vaccination Officers.

Mr. PETO asked the President of the Local Government Board whether the gratuity he was now suggesting that boards of guardians should pay to their vaccination officers was equal to the amount that the officer had lost in consequence of the operation of the Vaccination Act and Order, 1907.—Mr. BURNS replied: The gratuity which the Board has suggested amounts approximately to half the difference between the average annual amount of fees received before 1908 and the amount of those received since.

Mr. C. DUNCAN: Can the right honourable gentleman state when the arrangement will come into operation?—Mr. BURNS: No, sir, not at this moment.

Cerebro-spinal Meningitis.

Mr. GOLDSMITH asked the President of the Local Government Board whether any inquiries had been made into the causes of the recent outbreak of cerebro-spinal meningitis in Suffolk.—Mr. BURNS answered: The outbreak of disease in Suffolk has been the subject of correspondence and inquiries on the part of the Board and of the local authorities concerned. In a large number of districts of Suffolk both cerebro-spinal fever and poliomyelitis have recently been made compulsorily notifiable, and pathological material has in several instances been sent to the Board for examination. The evidence points to the conclusion that the disease which has recently occurred is poliomyelitis and not cerebro-spinal fever. This disease generally is at present the subject of reports by medical inspectors of the Board which will shortly be issued.

National Insurance Bill.

Viscount WOLMER asked the Speaker whether the National Insurance Bill was a Money Bill within the meaning of the Parliament Act.—The SPEAKER said in reply: The National Insurance Bill, as it now stands, is not, in my opinion, a Money Bill within the definition of Section I. of the Parliament Act.

THURSDAY, NOV. 23RD.

The Notification of Phthisis in Scotland.

Mr. E. WASON asked the Lord Advocate whether it was the intention of the Local Government Board for Scotland to issue regulations making consumption a notifiable disease in Scotland in the same way as it had recently been made a notifiable disease in England.—Mr. URE said in reply: The Local Government Board for Scotland has for years urged upon local authorities the desirability of making pulmonary phthisis a notifiable disease, with the result that compulsory notification has already been applied and is in force over areas containing 57 per cent. of the population of Scotland. The Board has now under consideration the question whether the time has come for the issue of a general order on the lines suggested by my right honourable friend.

The Insurance Bill and the Medical Panel.

Mr. GRETTON asked the Secretary to the Treasury whether a medical man who served on a health committee under the National Insurance

Bill would under the proposed regulations be able to remain upon the panel of doctors appointed by the same health committee.—Mr. MCKINNON WOOD wrote in reply: Yes, sir, any duly qualified medical practitioner has the right to be included in the panel, which it is not quite accurate to describe as "appointed" by the health committee.

MONDAY, NOV. 27TH.

The Wrapping of Sweets.

Mr. EDMUND HARVEY asked the President of the Local Government Board whether his attention had been called to the conditions under which caramel wrapping was stated by the medical officer of Islington to be carried on in certain homes; whether he was aware that the work was done by persons suffering from infectious diseases and was therefore calculated to convey infection to the consumer; and whether any steps were being taken to deal with the matter.—Mr. MCKENNA said in reply: My right honourable friend has asked me to answer this question. The Home Office received from the medical officer of health of Islington a copy of his report on this matter, and inquiries have since been made into the conditions prevailing in this industry both in London and elsewhere. It appears that the work carried on in the cases referred to by the medical officer is not the wrapping of caramels, which owing to their soft nature could not be given to outworkers, but the wrapping of some kinds of cheap sweets. Only one maker has been found who employs outworkers on this work, and he employs some 30 or 40 outworkers under conditions which in many cases are extremely insanitary, and in some cases carry danger of infection. I propose to issue at once a draft Order extending the provisions of Sections 107, 108, and 110 of the Factory Act to this class of work.

Medical Officers to the Post Office.

Mr. EDMUND HARVEY asked the Postmaster-General whether the appointments of medical officers to the Post Office were regarded as political patronage, and whether, to avoid misunderstanding, he would arrange that public notice should be given before local appointments were made, enabling all duly qualified candidates to apply.—Mr. H. SAMUEL replied: Political influence is not allowed to enter into the selection of medical officers to the Post Office. Appointments are made solely with regard to the personal qualifications of the candidates and the proximity of their consulting-rooms to the Post-office premises. Vacancies for medical officers to the Post Office in the London district are advertised in the local press. In the provinces applications are generally invited from all suitable local medical practitioners.

TUESDAY, NOV. 28TH.

Malaria-bearing Mosquitoes at Port Said.

Mr. RAMSAY MACDONALD asked the Secretary of State for Foreign Affairs whether he had received information that malaria-bearing mosquitoes had reappeared at Port Said owing to the negligence of the sanitary authorities; and whether he would communicate with Lord Kitchener on the subject.—Sir EDWARD GREY said in reply: I have been informed that mosquitoes have reappeared at Port Said, but I cannot say owing to what cause, nor do I know whether they are of a malaria-bearing species. I am inquiring of Lord Kitchener as to the facts.

Certifying Surgeons.

Lord HENRY CAVENDISH-BENTINCK asked the Secretary of State for the Home Department how many certifying surgeons hold other public appointments, including all the public medical officers mentioned in the memorandum of the Local Government Board to the local authorities issued in December, 1910.—Mr. MCKENNA replied: I regret that I am not able to give the noble lord the information he asks for, but the figures of certifying surgeons in England and Wales holding the posts of medical officer of health and district medical officer is as follows:—The number of certifying surgeons holding both posts is 247; the number holding the post of medical officer of health only is 141; the number holding the post of district medical officer only is 502. The total number of certifying surgeons in England and Wales, apart from medical men appointed to act as certifying surgeon for an institution under Section 5 of the Factory Act of 1907, is 1280.

WEDNESDAY, NOV. 29TH.

The Provision of Sanatoria.

Mr. GOLDMAN asked the Secretary to the Treasury whether steps would be taken immediately after the passing of the Insurance Bill into law to increase or extend sanatoria throughout the country to meet the needs of those who would be entitled to immediate sanatorium benefit under the Bill, and if he could state the nature of the steps which would be taken.—Mr. MCKINNON WOOD answered: The answer to the first part of the question is in the affirmative. The precise nature of the steps to be taken depends upon the Insurance Commissioners and the Local Government Board.

BOOKS, ETC., RECEIVED.

APPLETON, D., AND CO., New York and London.

The Diseases of Infancy and Childhood. For the Use of Students and Practitioners of Medicine. By L. Emmett Holt, M.D., Sc.D., LL.D., Professor of Diseases of Children in the College of Physicians and Surgeons (Columbia University), New York. Assisted by John Howland, A.B., M.D., Professor of Diseases of Children in Washington University, St. Louis. Sixth edition, fully revised. Price, cloth, 25*s.* net.

BAILLIÈRE, TINDALL, AND COX, London.

A Manual of Diseases of the Eye. By Charles H. May, M.D., New York, and Claud Worth, F.R.C.S. Eng., Consulting Ophthalmic Surgeon to the West Ham and East London Hospital. Third edition. Price 10*s.* 6*d.* net.

CHURCHILL, J. AND A., London.

Materia Medica, Pharmacy, Pharmacology, and Therapeutics. By W. Hale White, M.D. Lond., M.D. Dub. (Hon.), Senior Physician to and Lecturer on Medicine at Guy's Hospital. Twelfth edition. Price 6*s.* 6*d.* net.

A Short Practice of Medicine. By Robert A. Fleming, M.A., M.D., F.R.C.P.E., F.R.S.E., Lecturer on Practice of Medicine, School of the Royal Colleges, Edinburgh. Second edition. Price 12*s.* 6*d.* net.

CURRIE, JOHN, 16, Teviot-place, Edinburgh.

Outlines of Early Development. For Obstetric Students. By R. W. Johnstone, M.A., M.D., F.R.C.S.E., M.R.C.P.E., Assistant to the Professor of Midwifery, University of Edinburgh. With a Preface by Sir J. Halliday Croom, Professor of Midwifery, University of Edinburgh. Price 1*s.* 6*d.* net.

DULAU AND CO., LIMITED, 37, Soho-square, London, W.

Department of Applied Statistics, University College, University of London. Drapers' Company Research Memoirs. Studies in National Deterioration. VII. The Intensity of Natural Selection in Man. By E. C. Snow, M.A., Biometric Laboratory, University College, London. Price 3*s.*

GREEN, WILLIAM, AND SONS, Edinburgh and London.

The Control and Eradication of Tuberculosis. A Series of International Studies. By Many Authors. Edited by Halliday G. Sutherland, M.D., Medical Officer to the St. Marylebone Anti-Tuberculosis Dispensary. Price 15*s.* net.

HERBERT AND DANIEL, 21, Maddox-street, London, W.

Modern Surgery and its Making. A Tribute to Listerism. By C. W. Saleeby, M.D., F.R.S.E. Price 10*s.* 6*d.* net.

HODDER AND STOUGHTON, London, New York, and Toronto.

The Life of Dr. Arthur Jackson of Manchuria. By the Rev. Alfred J. Costain, M.A. With a Preface by the Rev. William Watson, M.A. Price 2*s.* net.

HORN, JOHN, LIMITED, 149, Howard-street, Glasgow.

Diet Charts. For the Use of Physicians. Part I. By J. Cralk Taylor, M.B. Glasg. Price 1*s.* net.

KEGAN PAUL, TRENCH, TRÜBNER, AND CO., LIMITED, London.

Practical Hints for Pastoral Work Among the Sick. By H. Gordon Mackenzie, M.A., M.B.; and Notes and Suggestions on Visiting the Sick, together with Short Service and Private Devotions for the Sick. Compiled by Rev. Archibald O. Hayes, M.A., Vicar of Holy Trinity, Lambeth, and Hospitaller of St. Thomas's Hospital. With an Introduction by Sir Dyce Duckworth, Bart., M.D., LL.D. Price not stated.

LEONARD, W. M., Publisher, Boston.

Case Histories in Neurology. A Selection of Histories setting forth the Diagnosis, Treatment, and Post-mortem Findings in Nervous Disease. By E. W. Taylor, A.M., M.D., Instructor in Neurology, Harvard Medical School. Price not stated.

LEWIS, H. K., London.

A Handbook of the Diseases of the Eye and Their Treatment. By Sir Henry R. Swanzy, A.M., M.D., D.Sc., Past-President of the Royal College of Surgeons in Ireland; and Louis Werner, M.B., F.R.C.S.I., Sen. Med. Univ. Dub., Ophthalmic Surgeon to the Mater Hospital, Dublin. Tenth edition. Price 12*s.* 6*d.* net.

LIPPINCOTT (J. B.) COMPANY, Philadelphia and London.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BADLEY, S. B., M.B., Ch.B. Vict., has been appointed Junior House Surgeon at the Manchester Royal Infirmary.

BANNERMAN, JAMES, M.B. Edin., has been appointed Medical Officer to the Stanhope and Weardale Joint Isolation Hospital.

DIGGLE, F. H., M.B., Ch.B. Vict., has been appointed House Surgeon to Special Departments at the Manchester Royal Infirmary.

FARRIES, J. STOTHART, L.R.C.P. & S. Edin., has been appointed Medical Superintendent of the Minda Institution for the Feeble-minded and Epileptic, Adelaide, South Australia.

GALBRAITH, THOMAS, M.B Edin., has been appointed Honorary Vaccine Therapist to St. John's Hospital for Diseases of the Skin.

HENDERSON, ROBERT G., M.B., Ch.B. Aberd., F.R.C.S. Edin., has been appointed Assistant Surgeon to the Royal Infirmary, Oldham.

HIGGINS, T. T., M.B., Ch.B. Vict., has been appointed Accident Room House Surgeon at the Manchester Royal Infirmary.

KAUNTZE, W. H., M.B., Ch.B. Vict., has been appointed Junior House Surgeon at the Manchester Royal Infirmary.

MAITLAND, LYTTON, M.B., B.S. Lond., has been appointed Resident Medical Officer at the London Fever Hospital.

MORGAN, T., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Llandovery District of the county of Carmarthen.

PEDLER, H. C. G., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician at University College Hospital.

PRANCE, G. H., M.D., M.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Weston-super-Mare District of the county of Somerset.

RAMSBOTTOM, A., M.D. Vict., M.R.C.P. Lond., has been reappointed Assistant Medical Officer to the Manchester Royal Infirmary.

REID, W. J., M.B., Ch.B. Aberd., has been appointed Cancer Research Officer at the Manchester Royal Infirmary.

RIGG, J. R., M.B., Ch.B. Vict., has been appointed Senior House Surgeon at the Manchester Royal Infirmary.

ROBSON, J. D., M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Dumfries District of the county of Dumfries.

SCOTT, J. B., M.B., Ch.B. Vict., has been appointed House Physician at the Manchester Royal Infirmary.

SNEATH, W. A., M.B., Ch.B. Vict., has been appointed Senior House Surgeon at the Manchester Royal Infirmary.

THOMPSON, G. K., M.B., Ch.B. Vict., has been appointed House Physician at the Manchester Royal Infirmary.

WILLAN, R. J., M.S. Durh., F.R.C.S. Eng., has been appointed Demonstrator of Surgical Pathology in the University of Durham College of Medicine, Newcastle-upon-Tyne.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BARNSLEY, BECKETT HOSPITAL.—Second House Surgeon, unmarried. Salary £100 per annum, all found.

BATH, EASTERN DISPENSARY.—Resident Medical Officer, unmarried. Salary £150 per annum, with rooms, coals, gas, and attendance.

BATH ROYAL UNITED HOSPITAL.—House Surgeon. Salary £80 per annum, with board, residence, and washing.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon, unmarried. Salary £200 per annum, with rooms, fire, light, and attendance.

CROYDON GENERAL HOSPITAL.—Additional Member of Honorary Medical Staff.

DONCASTER, ROYAL INFIRMARY AND DISPENSARY.—Senior House Surgeon and Assistant House Surgeon. Salaries respectively £100 and £80 per annum, with board, lodging, and washing.

FLORENCE NIGHTINGALE HOSPITAL FOR GENTLEWOMEN, 19, Lissongrove, N.W.—House Surgeon. Salary £100 per annum.

GLASGOW, SCHOOL BOARD OF.—Female Lecturers on Hygiene and Home Nursing. 7*s.* 6*d.* per lecture.

GOVAN DISTRICT ASYLUM, Hawkhead, near Paisley.—Second Assistant Medical Officer. Salary £150 per annum, with rooms, board, laundry, and attendance.

GREAT YARMOUTH HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

GRIMSBY AND DISTRICT HOSPITAL.—Junior House Surgeon. Salary £80 per annum, with board, lodging, attendance, and washing.

HELLINGLY, EAST SUSSEX COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £160 per annum, with board, apartments, washing, and attendance.

HENDON, N.W., CENTRAL LONDON SICK ASYLUM.—Assistant Medical Officer. Salary £120 per annum, with board and residence.

HÔPITAL FRANÇAIS, 172, Shaftesbury-avenue, W.C.—Resident Medical Officer, unmarried, for six months. Salary £100 per annum, with full board and laundry.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician.

HULL ROYAL INFIRMARY.—Assistant House Surgeon. Salary at rate of £80 per annum, with board and lodging.

INDIAN MEDICAL SERVICE.—Twelve Commissions.

ITALIAN HOSPITAL, Queen-square, London, W.C.—Honorary Assistant Physician.

KENSINGTON DISPENSARY AND CHILDREN'S HOSPITAL.—Vacancy on the Honorary Medical Staff.

LEICESTER INFIRMARY.—Assistant House Physician for six months. Salary at rate of £80 per annum, with board, apartments, and washing.

LINCOLN COUNTY HOSPITAL.—Junior House Surgeon, unmarried, for six months. Salary at rate of £75 per annum, with board, residence, and washing.

LONDON LOCK HOSPITAL.—House Surgeon to Female Hospital. Also House Surgeon to Male Hospital. Salary in each case £100 per annum, with board, lodging, and washing.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W.—Surgical Registrar. Salary at rate of 40 guineas per annum. Also Resident Medical Officer. Salary £120 per annum, with board, lodging, and washing.

MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT AND CHEST.—Assistant Medical Officer and Pathologist. Salary £60 per annum.

NAPSBURY, MIDDLESEX COUNTY ASYLUM, St. Albans.—Assistant Medical Officer. Salary £180 per annum, with board, lodging, washing, and attendance.

NORTHAMPTON GENERAL HOSPITAL.—Senior Resident Medical Officer, unmarried. Salary £120 per annum, with apartments, board, washing, and attendance.

NOTTINGHAM GENERAL HOSPITAL.—Assistant House Surgeon. Salary £100 per annum, with board, lodging, and washing.

POPLAR WORKHOUSE, High-street, Poplar.—Medical Officer. Salary £250 per annum.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Assistant Resident Medical Officer for four months. Salary at rate of £50 per annum, with board, residence, and washing.

ROYAL EAR HOSPITAL, Soho.—Honorary Visiting Physician. Also Honorary Pathologist.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Female Medical Registrar and Junior Obstetric Assistant.

ST. BARTHOLOMEW'S HOSPITAL.—Chief Assistants and Clinical Assistants for Aural Out-patient Department.

ST. MARK'S HOSPITAL FOR CANCER, FISTULA, AND OTHER DISEASES OF THE RECTUM, City-road, London, E.C.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

ST. PANCRAS AND NORTHERN DISPENSARY, 126, Euston-road.—Honorary Physician.

ST. PAUL'S HOSPITAL FOR SKIN AND URINARY DISEASES, Red Lion-square, W.C.—Clinical Assistants.

SALFORD UNION INFIRMARY.—Senior Assistant Medical Officer, unmarried. Salary £130 per annum, with apartments, attendance, and rations.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician, unmarried. Salary £60 per annum, with board, lodging, and washing.

SHEFFIELD ROYAL INFIRMARY.—Junior Resident Medical Officer. Salary £60 per annum.

SHEFFIELD UNION HOSPITAL, Firvale, Sheffield.—Resident Medical Officer. Salary, if married, £375 per annum, with house partly furnished, coals, light, laundry, &c.; if single, £300 per annum, with apartments, rations, and the other usual residential allowances.

SHREWSBURY, COUNTY ASYLUM.—Second Assistant Medical Officer, unmarried. Salary £170 per annum, with board, apartments, washing, attendance, &c.

SUNDERLAND ROYAL INFIRMARY.—House Physician for six months. Salary £80 per annum, with board, residence, and laundry.

SWANSEA GENERAL AND EYE HOSPITAL.—House Surgeon. Salary £75 per annum, with board, washing, and attendance.

THROAT HOSPITAL, Golden-square, W.—Honorary Assistant Surgeon.

VIRGINIA WATER, SURREY, HOLLOWAY SANATORIUM FOR THE INSANE.—Junior Assistant Medical Officer (female). Salary £150 per annum, with board, lodging, laundry, attendance, &c.

WADSLEY, NEAR SHEFFIELD, WEST RIDING ASYLUM.—Fifth Assistant Medical Officer. Salary £140 per annum, with board, &c.

WIGAN, ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY.—Assistant Honorary Surgeon in the Eye, Ear, and Throat Departments.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Kingsbridge, in the county of Devon; at Longtown, in the county of Cumberland; and at Chatham, in the county of Kent.

Births, Marriages, and Deaths.

BIRTHS.

DOW.—On Nov. 26th, at Bentham, Yorks, to James Fleming Dow, M.D., and Catherine Dow—a daughter.

HUGHES.—On Nov. 26th, at Barnsley Hall, Bromsgrove, Worcestershire, to Dr. and Mrs. Percy T. Hughes—a daughter.

MARRIAGES.

BREMER—MCKENZIE.—On Oct. 14th, at St. George's Presbyterian Church, Johannesburg, Karl Bremer, M.B., B.S. Lond., of Cradock, Cape Province, to Alice Elizabeth, eldest daughter of Mr. and Mrs. Thos. McKenzie, Johannesburg.

DEATHS.

HUBERT.—On Nov. 22nd, suddenly, of heart failure, at Billingshurst, Sussex, William Henry Hubert, M.R.C.S. Eng., L.S.A., aged 66.

MARTIN.—On Nov. 23rd, at Claremont-place, Sheffield, John W. Martin M.D., aged 65.

Notes, Short Comments, and Answers to Correspondents.

VITAL STATISTICS OF SEYCHELLES.

ACCORDING to the Blue-book for 1910 of the Seychelles Islands (the total area of which is estimated at 148½ square miles) the population is 22,620—11,522 males and 11,098 females. The births during the year numbered 709, being 31·35 per 1000, and the deaths 368, being 16·26 per 1000. There were 119 marriages. The density of the population is 145 to one square mile. The rainfall was again short, reaching only 83·31 inches. There was a severe drought from June to October. In the latter month only 0·03 inch was recorded. The mean temperature was 79·5°. April was the hottest and August the coolest month of the year. There were 480 in-patients treated in the Victoria Hospital in 1910, exceeding by 100 the number in 1909, which was the highest recorded. There were 30 deaths, giving a percentage of 6·25. Sixteen persons suffering from beri-beri were treated, of whom three died. This disease appears to be decreasing rapidly with the use of nitrogenous foods. There were 11 cases of, and three deaths from, tubercular complaints, and two deaths out of eight cases of cancer. There are six dispensaries, at which 3196 persons received treatment. The numbers show a large decrease (25 per cent.), which is satisfactory, inasmuch as it has always been evident that the privilege of free treatment has been abused. A small outbreak of beri-beri on Coetivy Island was promptly checked by a change of diet amongst the labourers. An assistant medical officer visited the island, and with the substitution of Bengal for Rangoon rice no further cases occurred. The chief medical officer notes that all previous cases were of the œdematous type, while all the cases from Coetivy were of the emaciated type. Tuberculosis appears to be stationary, but the medical officers report an increase in venereal disease and in the number of infants suffering congenitally. Nine cases were treated in the Round Island Leper Asylum with one death. The home is well kept and is constantly visited by the assistant medical officer at Praslin. Experiments are being made with the new treatment—nastin. These experiments are of too recent a date for any pronouncement to be made, but the patients take readily to the treatment. The lunatic asylum is now in full working order. Two males and one female were discharged as recovered, one male patient died, and 22 patients remained at the close of the year.

ROYAL MICROSCOPICAL SOCIETY: AN INTERESTING FIND.

AT the meeting of this society on Nov. 15th Mr. C. F. Rousselet, the curator, exhibited and described an old microscope bearing the name of Andrew Pritchard, which Captain Warrington had discovered in India and had presented to the society. It was probably made by Andrew Ross for Pritchard, who sold microscopes made for him by Ross and Hugh Powell. The date to be assigned to it would be between 1834 and 1838. Mr. Rousselet also described another microscope from India lent by Mr. A. H. Lethbridge. It was a combination of a pocket telescope and microscope. The eyepiece of the telescope, being removed and screwed into a "drum" form of stand, constituted a low power microscope of itself, and on removing the field lenses of the eyepiece "French buttons" can be screwed on giving higher magnifications. The name inscribed on the apparatus is Charles Nephew and Co., Calcutta. The date is uncertain, but would be some time after the introduction of the "French button." The society exhibited under microscopes a number of slides of rock sections from Australasia presented by Mr. H. J. Grayson and cut by him by his improved apparatus. Mr. J. E. Barnard read a paper on a Geometric Slide Photomicrographic Apparatus. Mr. Barnard said the apparatus was designed throughout on the principle of the geometric slide as enunciated by Lord Kelvin and Tate. The base of the apparatus was formed of two castings designed on the girder principle, braced together at each end and in the middle. The portion to carry the microscope was also formed by a pair of castings braced together in the same way. Great rigidity was obtained, and the whole apparatus would move together if subjected to shock or vibration. Rods were fastened down on the top of the castings to support the apparatus, and the camera slid along these on two V grooves on one side and on a plane surface on the other side. The camera was supported on vertical rods fixed on the geometric slides. The apparatus could be used equally well as a horizontal or vertical camera or at an angle of 45°. A paper on Fridericia by Rev. Hilderic Friend, F.L.S., was read. The genus Fridericia was created by Michaelson in 1889 to receive certain species of Enchytraeids, 11 in number, possessed of dorsal pores and having sets of unequal lengths. In 1895 Beddard reckoned 12 species, but not one was known as British. Moore, Friend, and others added to the list, which in 1900 stood at 21. Bretscher, Issel, and others then took up the study, and at the present time some 70 or 80 species of Fridericia are known to science. The largest is F. magna, Friend, which has been found in England, Ireland, and Scotland, but so far has not been reported abroad. The author, whose researches into this genus began in 1896, here reports no fewer than 30 species found up to the present time in the British Isles. Some of these are new to science, and a series of keys is appended to enable the student readily to distinguish the allied species.

THE GUILD OF THE BRAVE POOR THINGS.

H.R.H. Princess Louise, Duchess of Argyll, has promised to visit the exhibition and sale to be held in support of the Guild at 19, Grosvenor-square, by kind permission of Mrs. Cazalet, on Monday, Dec. 4th, from 3 to 6 P.M. The sale will include fine needlework and woodwork from the Heritage Craft Schools in Sussex, of which Mrs. Cazalet is the patroness, and copper, silver, and basket-work made by Guild members at the various branches. The Guild of Play children will give a recital of dance carols and court dances at 6 P.M.

GUARDIANS AND PRIVATE PATIENTS.

THE Lewisham board of guardians recently considered an interesting point concerning a woman of whom it was reported by the clerk to the board that she was not destitute, although it had been decided that she should be attended by the district medical officer. On her decease it was ascertained that she had left a sum of money amounting to £60, and her relative, who benefited under the will, had refunded to the board £3 3*s*. for the doctor's attendance. It was argued that the fees should be handed over to the district medical officer as the board had no right to make a profit out of persons o means, who should be the private patients of the medical profession. The board, however, decided to take no action.

ESPERANTO.

MEDICAL Esperantists, both in this country and abroad, will regret to hear that, owing to pressure of duties, Colonel John Pollen, C.I.E., has resigned the presidency of the British Esperanto Association.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for the next few months:—

Dec. 4th–9th (Havana, Cuba).—American Public Health Association.
" 12th–14th (Washington, D.C.).—Southern Surgical and Gynæcological Association.
" 19th–23rd (Moscow).—Third Pan-Russian Therapeutical Congress.
" 27th–30th (Baltimore).—American Physiological Society.

In 1912:—

Jan. 20th–27th (Hong-Kong).—Second Biennial Congress of the Far Eastern Association of Tropical Medicine.
Feb. 13th–14th (London).—Central Poor-Law Conference.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.

PATHOLOGICAL SECTION (Hon. Secretaries—J. C. G. Ledingham, A. E. Boycott): at 8.30 P.M.

LABORATORY MEETING at the Imperial Cancer Research Fund, Victoria Embankment, West Entrance (opposite Savoy Hotel).

Dr. J. A. Murray: (1) Relative Frequency of Cancer of the Mammæ in Mice of Cancerous and Non-cancerous Ancestry; (2) Results of Inoculating a Mixed Emulsion of Spontaneous Tumours into the Mice Providing them; (3) Results of Operative Treatment of Carcinoma Mammæ in the Mouse; (4) Tumours showing Multiple Differentiations—Metaplasia.

Dr. B. R. G. Russell: (1) The Reaction of Animals to Tumour Parenchymata of Various Types of Growth; (2) Failure to Obtain Evidence for Passive Immunity against the Inoculation of Cancer.

Mr. W. H. Woglom: (1) The Curves of Resistance to the Implantation of Carcinoma as Induced by Normal and Tumour-Tissue respectively; (2) The Histology of the Site of Inoculation of Carcinoma in Normal and Resistant Rats; (3) Resistance Induced Subcutaneously to the Implantation of Cancer is Effective against Implantation into Internal Organs.

Dr. E. F. Bashford: (1) The Modes of Growth and the Relative Rates of Growth of 85 Propagable Tumour-strains; (2) The Experimental Test of the Validity of the Assumption of a Differential of Avidity as Explanatory of Tumour Growth; (3) The Variability of Tumour Cells during Propagation.

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—J. H. Targett, W. W. H. Tate), at 11, Chandos-street, W., at 8 P.M.

Specimens:

Dr. Hedley: Cervix Adherent to Posterior Vaginal Wall.

Dr. Barris; Solid Malignant Growth of Ovary.

Dr. Macnaughton-Jones: (1) Section of Carcinoma of Vulva; (2) Cyst Growing from Remains of a Resected Ovary.

Dr. Walter Tate: Extra-uterine Gestation; Death of Fœtus near Term; Removal of Entire Sac Three Months Later.

Dr. Whitehouse: Ruptured Four Months' Gestation in Rudimentary Horn of Bicornuate Uterus.

Dr. Maxwell: Chorion-angioma of Uterus.

Dr. Herman: A Dissection of the Pelvic Fascia.

Short Communications:

Dr. Maxwell: Sequel to a Case of Cystic Degeneration of Chorion.

Dr. Eardley Holland: Case of Ovarian Pregnancy.

Dr. Whitehouse: Cases of Primary Carcinoma of Female Urethra.

FRIDAY.

GENERAL MEETING OF FELLOWS at 4.45 P.M.

Election of Candidates for Fellowship.

CLINICAL SECTION (Hon. Secretaries: James Galloway, Charles H. Fagge): at 8.30 P.M.

Cases:

Mr. Tilley: Four Cases illustrating Surgical Treatment of Chronic Empyema of the Nasal Accessory Sinuses. Demonstration by Direct Method of Papillomata of the Vocal Cords.

Mr. H. Morriston Davies: Case showing the Result of Operation for Dislocation of Patella.

Mr. H. J. Curtis: Case of Acute Periostitis of Rib with Separation of Sequestra (Non-tuberculous, Non-traumatic).

Mr. Edred M. Corner: Case of Healed Double Empyema.

Mr. R. P. Rowlands: Case of Perforated Jejunal Ulcer following Anterior Gastro-jejunostomy.

Mr. C. G. Watson: Case of Excision of Large Myeloid Sarcoma of the Ischium.

Cases will also be shown by Dr. J. Fawcett, Mr. Raymond Johnson, and others.

RONTGEN SOCIETY, Institution of Electrical Engineers, Victoria Embankment, W.C.

TUESDAY.—8.15 P.M., General Meeting. Paper:—Prof. W. H. Bragge: The Energy of the X Ray.

HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C.

WEDNESDAY.—8.30 P.M., Council Meeting. 9 P.M., Clinical and Pathological Evening.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.

THURSDAY.—4.15 P.M., Clinical Cases.

WIMBLEDON AND DISTRICT MEDICAL SOCIETY, Johnston's Rooms, 6, Broadway, Wimbledon.

FRIDAY.—9 P.M., Dr. R. W. Allen: Modern Methods of Treating Tuberculosis, with Special Reference to Pulmonary Tuberculosis and Tuberculins.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

WEDNESDAY.—5 P.M., Mr. R. Clement Lucas: Some Points in Heredity. (Bradshaw Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. L. Bunch: Clinique (Skin). 5.15 P.M., Lecture:—Dr. D. Forsyth: The Diagnosis of Organic Nervous Lesions.

TUESDAY.—4 P.M., Dr. W. H. Willcox: Clinique (Medical). 5.15 P.M., Lecture:—Mr. E. Lane: Syphilis d'Emblée.

WEDNESDAY.—4 P.M., Mr. G. E. Waugh: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. R. Maguire: The Solution of Calculi in the Urinary Passages without Operation.

THURSDAY.—4 P.M., Dr. H. Campbell: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. W. D'Oyly Grange: Some Disorders of the Liver and their Treatment.

FRIDAY.—4 P.M., Dr. G. Thompson: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. Dr. Simson: Diseases of Women. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Bidwell: Gastro-enterostomy and Duodenal Ulcer.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. Etherington-Smith: Clinical. (Lecture I.)

WEDNESDAY.—10 A.M., Dr. Simson: Gynæcological Demonstration. Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine. (Lecture V.)

THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery. (Lecture V.)

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. R. Lloyd: Administration of Anæsthetics.

SATURDAY.—10 A.M., Medical Registrar: Demonstration of Cases in Wards. Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. Bishop Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. E. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 3.15 P.M., Dr. R. Wells: Medicine. 2.15 P.M., Mr. R. Carling: Surgery. 4.15 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 4.30 P.M., Special Lecture:—Mr. Walton: Abdominal Anatomy.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Sir J. Rose Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—10 A.M., Radiography. 11 A.M., Dr. A. Davies: Pathological Demonstration. 2 P.M., Operations. Out-patient Demonstration:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. D. Gillies). 3 P.M., Pathological Demonstration (Dr. Duncan).

TUESDAY.—Clinic; 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld).; Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Lecture:—Dr. A. E. Giles: Pessaries.

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen): Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Mr. W. Steuart); Pathological Demonstration (Dr. Duncan). 5.30 P.M., Eye Operations (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappell).

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie); Pathological Demonstration (Dr. Duncan).

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Mr. W. Hampson: X Ray Epilation for Ringworm.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell; Bullous and Vesicular Eruptions—I., Urticaria; II., Pemphigus; III., Pompholyx; IV., Varicella.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST. Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. Perkins: Some Clinical Effects of Tuberculin.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. G. Stewart: Treatment of Muscular Paralysis.

FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. G. Stewart: Apoplexy.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Mr. J. G. French: Pharynx and Naso-pharynx.

FRIDAY.—3.45 P.M., Lecture:—Dr. Abercrombie: Pharynx and Naso-pharynx.

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Dr. C. H. Melland: Malaria. (Post-Graduate Clinic.)

OPERATIONS.

METROPOLITAN HOSPITALS.

Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The Bradshaw Lecture

ON

INTRATHORACIC TUMOURS AND ANEURYSMS IN THEIR CLINICAL ASPECT.

Delivered before the Royal College of Physicians of London on Nov. 2nd, 1911,

BY GRAHAM STEELL, M.D. EDIN., F.R.C.P. LOND.,

CONSULTING PHYSICIAN, MANCHESTER ROYAL INFIRMARY, AND EMERITUS PROFESSOR IN THE VICTORIA UNIVERSITY OF MANCHESTER.

MR. PRESIDENT, FELLOWS OF THE COLLEGE, AND GENTLEMEN,—My first duty is to express to you, Sir Thomas Barlow, my grateful thanks for the honour you conferred upon me by appointing me Bradshaw Lecturer for the present year. With the appreciation of an honour such as this there mingles, I fancy, in the minds of most recipients a sense of the greatness of the task which the appointment imposes. At any rate, it was so in my case.

My predecessor in office gave you an interesting sketch in words of Dr. William Wood Bradshaw, whose widow founded the lectureship in memory of her husband. Dr. Newton Pitt also showed his portrait, the representation of which in the *British Medical Journal* has made the profession at large acquainted with the outward personality of the man whose memory is perpetuated by this lectureship and "whose righteousness hath not been forgotten."

It so happened that the year in which I have the honour of being Bradshaw Lecturer is also the year in which I ceased, by the rules of the institution, to be a member of the acting staff of the hospital in the service of which I had been privileged to be for over 30 years. At such a time it is perhaps only natural that I should look backwards rather than forwards, and—dare I confess it!—clinical medicine seems to me at the present moment to be in danger of losing something of its old charm and, in the future, of losing much more. It was no other than Trousseau who exclaimed some 50 years ago in an address on medicine—"Pray, gentlemen, let us have a little more art, a little less science." Yet who would have welcomed with greater warmth such triumph of science as the introduction into practice of diphtheritic antitoxin? Indeed, "the individual withers, and the world is more and more." This is only evolution after all.

INTRODUCTORY REMARKS.

The subject I have chosen is a very practical one: "Intrathoracic Tumours and Aneurysms in their Clinical Aspect."

I regard aneurysms as tumours—only of a special kind and revealing themselves by special signs. The inclusion of aneurysms may be adversely criticised, but, I believe, I am right in regarding intrathoracic *aneurysm*, as soon as it exerts pressure on neighbouring structures—say the recurrent nerve—*as a tumour*. All who have had much acquaintance with the two conditions—neoplasm and aneurysm within the chest—will, I think, admit the difficulty occasionally experienced in distinguishing between them, even when the greatest care is taken.

Notwithstanding the great help in diagnosis afforded by recent discoveries in physical science and their utilisation in clinical medicine, for years to come, I fancy, the manifestations of intrathoracic tumours will still be investigated at the bedside in the old way—by the *symptoms* and by the *signs* they occasion, or in other words, *subjectively* and *objectively*, though the division at times proves rather arbitrary.

While including aneurysms with neoplasms as intrathoracic tumours, it is the latter (neoplasms) that I wish specially to consider, inasmuch as, paradoxically, aneurysms are common and tumours comparatively rare. The distinction between the two is, however, a matter of considerable practical importance in view of the fact that aneurysms not rarely admit of at least having their symptoms much relieved by treatment and of a useful life being considerably prolonged, while the downward progress of the patient with intrathoracic neoplasm is seldom even interrupted and our therapeutic endeavour is too often limited to the promotion of euthanasia, albeit without any shortening of life. If it be the first duty of the physician to "obviate the tendency to death" of his patient, then surely the second is to relieve his sufferings. Whether we have regard to intensity of actual pain, such as the pain of angina pectoris, or to its persistence, as in aneurysm grinding the vertebræ, or to suffering other than pain, such as suffocation and consequent air-hunger, in the whole field of clinical medicine no class of diseases can be compared with that we have under consideration in potency of production of pain and suffering. Even this is not all: the duration of such pain and other sufferings may be great, whether they be persistent, remittent, or intermittent.

No longer ago than 1889 the writer of one of the best known monographs on the subject, "Affections of the Mediastinum," Dr. Hobart Amory Hare, remarked that "for some unaccountable reason this subject has remained a field in which but few workers have toiled, and whose surface is therefore almost barren." Since these words were written no doubt several very valuable contributions have been made to the study and literature of the subject, among which I would mention Sir Douglas Powell's and Dr. Frederick Roberts's articles in Allbutt and Rolleston's "System of Medicine," the late Dr. Lindsay Steven's contributions in the *Glasgow Medical Journal*, and most recently the contribution of Dr. Newton Pitt in his Bradshaw lecture of last year.

With these introductory remarks I will now plunge *in medias res*.

PAIN.

It is customary to consider symptoms before signs, and in the clinical investigation of the former one has to consider the past as well as the present. I will begin with *pain*, the most *subjective* of all symptoms. Pain is seldom altogether absent in the course of intrathoracic tumours. One may say indeed that it is *never* absent if we include under the term such distresses as dyspnœa and insomnia. Here, however, I use the word in the conventional sense. In inquiring about this symptom in the study of a case one has to bear in mind the difficulty experienced by patients in describing their painful sensations even when present at the moment. How much greater must this difficulty be experienced when a remote pain is being described? As has been said, to recall such sensation in full intensity would be tantamount to suffering it again, and we may conclude that Nature has mercifully decreed that there shall be vague and indefinite recollection of even a severe pain. So, I fancy, clinicists till recently were apt to underrate the value of the symptom—pain—and we owe a debt of gratitude to Dr. Henry Head for the way in which he has shown how fruitful in diagnosis may be the careful investigation of this symptom, the "inwardness" of which, to use Sir William Gairdner's expression, exceeds that of all others. Speaking generally, I think it may be stated that aneurysmal tumours are the more productive of pain, and in their case not only is the frequency of pain greater, but its intensity and its persistency also. Yet the seeming caprice of pain, even with regard to its mere presence, must be borne in mind, and from time to time one is forced to marvel, in the presence of its abundant physical causes, at the absence of the symptom—such cause, for instance, as a projecting aneurysmal tumour, which by its slow terebrating action has gradually but effectively absorbed alike sternal bone and costal cartilage. In striking contrast with such painlessness is the common long-drawn-out agony of aneurysmal pressure on the spine. Actual pain is certainly in frequency, and specially in intensity, much less characteristic of neoplasm than aneurysm, though suffering other than pain—yet quite as great, if not greater—is the common accompaniment of neoplasm, for instance, when it compresses the trachea or superior vena cava.

Speaking of intrathoracic tumour in general, different types of pain are met with, the chief of which I will only very briefly enumerate. 1. There may be referred pain—for instance, angina pectoris, which is by no means rare in aneurysms involving the ascending aorta. My experience would lead me to believe that the coronary orifices are always involved in such cases, but I do not wish to be dogmatic, especially in view of the fact that I have had two cases of typical angina pectoris in girls with mitral stenosis as the only cardiac lesion, one of whom died and

was found to have perfectly sound coronary orifices and arteries. Pain, and especially tenderness in Head's "inferior laryngeal triangle," should be remembered and inquired for, and if present, associated with probable implication of the transverse portion of the arch by aneurysm. 2. There may be pain, not referred, due to direct pressure on somatic nerves, such as is apt to occur in aneurysm of the descending thoracic aorta or secondary implication of the spine by neoplasm. Interference with other afferent functions of these nerves may be discovered, later, on objective examination. 3. There is the all-important pain, due to pressure directly upon bone, especially the spine. It is a trite saying that long-continued persistent pain in the back should make one think of aneurysm, unless there has already been neoplasm in some other part of the body. 4. Lastly, one cannot ignore the fact, I think, that severe, seemingly local, pain has been complained of in rare cases of rupture of the internal coat of the aorta, although the fact hardly concerns us in our present consideration.

While definite and persistent pain is, then, much more common in the case of aneurysm than neoplasm, indefinite pain and, still more frequently, distress, that can hardly be called pain, are seldom absent in the case of the latter. In the earlier stages of a case of aneurysm, moreover, indefinite fleeting and recurrent pains about the upper part of the chest, shoulders, upper arms, and neck are so common as, at least, to suggest a careful examination for the signs of aneurysm when they have been complained of.

I would remind you, lastly, in the consideration of pain as a symptom of intrathoracic tumour, of the occasional *occipital pain* suffered by patients the subjects of aneurysm of the arch. Twice I have known this symptom so severe as to be the most prominent of the case. The headache is not that common in heart cases and associated with irritation of the tenth dorsal spinal segment from a congested liver. Dr. Head states that when the third cervical segment of the cord is involved, the pain is found to "shoot from the back through the head to the centre of the forehead." From the description I have received from patients with aneurysm of the arch, the pain seemed to be essentially occipital. The pain of secondary pleural and possibly of lung conditions need only be mentioned.

DYSPNŒA.

Among the symptoms of intrathoracic tumour dyspnœa is entitled to an important place. Moreover, it occurs not in one form, but in various forms, and these may be met with in combination. If we consider the effects of obstruction situated, so to speak, at the root of the bronchial tree, on the one hand, and contrast them with the effects of the cutting off, and withdrawing from function, of a large portion of the vesicular field for oxygenation, on the other hand—types of dyspnœa exemplified respectively by laryngeal obstruction in croup and by pneumonia—we have the two extremes of dyspnœic types met with in intrathoracic tumour. But between these there are many intermediate varieties—such, for instance, as occur in ordinary bronchitis with much secretion in the intermediate bronchi. Those types of dyspnœa in which the obstruction is at the trunk or in the larger branches are, in common language, designated *laboured respiration*, and they occur, as might be foreseen, frequently in cases of intrathoracic tumour. On the other hand, when such obstruction has affected one main bronchus and has led to the *complete* withdrawal from function of a whole lung, while the trachea and other bronchus does not come directly under the influence of the obstruction, such dyspnœa as there may be will be expressed by simple frequency of respiration, each act being rapidly and easily performed. When it is remembered that in the first or tracheal type of dyspnœa each act of respiration becomes a laboured struggle, it is obvious that great frequency of respiration is impossible, though it is true that when the respiratory acts are failing, the element of struggle being less pronounced, their frequency may again increase at the expense of their efficiency.

Effusion into the pleura is a common complication of intrathoracic tumour and diminishes the vesicular field and *per se* should induce dyspnœa of the pneumonic type. The two types of dyspnœa contrasted as stated may, however, be present together in varying proportion, but the laboured type is the more subjective and appeals more to the patient, at any rate while he is at rest.

When present, the stridor of tracheal obstruction predominates over all other respiratory sounds and may be heard at a great distance from the patient. It is important to note whether stridor is present with both inspiration and expiration, or with inspiration only, the latter condition pointing to paralytic glottic obstruction. Adventitious sounds, other than rhonchi, are not common, and their absence or ill-development under the circumstances may be suggestive in diagnosis.

If there be obstruction in the trunk or larger branches of the bronchial tree as the result of intrathoracic tumour, there is commonly observed the familiar "antero-lateral inspiratory retraction" of the lower part of the chest and exaggerated action of the diaphragm so well described by Dr. Sibson, who carefully distinguished between diaphragmatic "effort" and diaphragmatic "descent," as exemplified by abdominal protrusion. Sibson well remarked that "this diminution of abdominal protrusion with manifestly increased diaphragmatic effort allies in this respect emphysema and bronchitis with cases of extreme laryngeal obstruction, in which the same phenomena present themselves."[1]

One knows how in the case of simple copious pleuritic effusion any sign of interference with the function of the unaffected lung becomes a danger-signal, urgently calling for removal of the fluid, and this, though such sign may be only an occasional rhonchus. So in intrathoracic tumour, implication of the lung alone acting is of great moment. There may be only bronchitis or there may be œdema of the lung tissue itself, or there may be both conditions in varying proportion, but in any case asphyxia is threatened.

It is a remarkable fact that, even when one would think partial obstruction to the trachea or a main bronchus must be permanent and little varying, paroxysmal exacerbations are apt to recur from time to time. This occurrence is much more common in cases of aneurysm than of solid growth. Such attacks have been attributed to plugs of secretion becoming engaged at the site of obstruction, but this condition can hardly explain all cases. A most striking feature of these cases is the relief often afforded by the hypodermic injection of morphine and atropine.

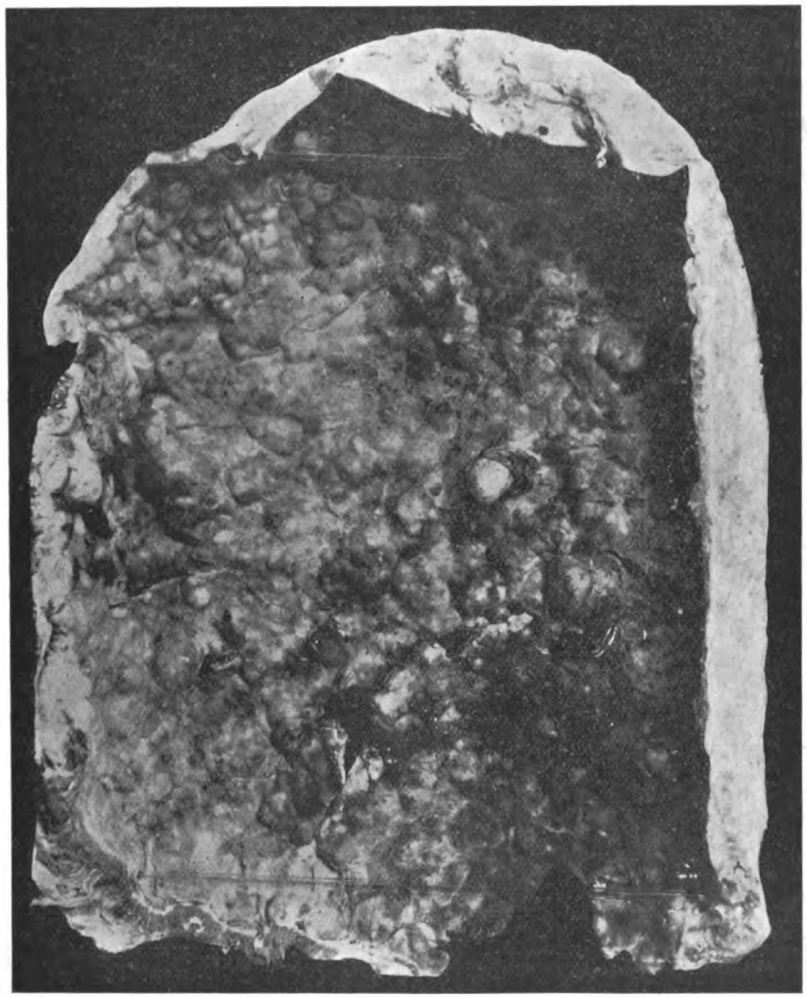
Paroxysms of dyspnœa again may form the only evidence of an aneurysm situated at the posterior descending portion of the arch, in cases in which even accentuation of the aortic second sound (to be considered later) is absent, inasmuch as the aorta between the valves and the sac is not dilated. Such paroxysms are often described as "asthma." I once had the curious experience of, within a fortnight, having two patients under my care in hospital suffering from such paroxysmal dyspnœa due to the cause in question. In the first case the cause of the dyspnœa which resembled a cardiac dyspnœa, though no signs of heart disease were obtainable, was not recognised; in the second it was recognised, because the first, having proved fatal, had taught its lesson by autopsy. In both these cases an aneurysm of the posterior part of the arch had compressed the lower end of the trachea and left bronchus. These two cases presented the best examples I have met with of what Sir William Broadbent called the "aneurysm of symptoms." I take it they exemplified, too, the condition that is least incorrectly included under "asthma" and described as a symptom of intrathoracic tumour, specially aneurysm.

As a matter of clinical experience it will be found that dropsy of the lower extremities and trunk is not rarely observed towards the termination of a case of intrathoracic tumour that does not interfere directly with the inferior vena cava. In the skiagram I show there may be seen a marked projection to the right of the sternum, just below an aneurysmal similar projection, and due to dilatation of the right auricle as a part of general cardiac dilatation. In one case (neoplasm) in which a systolic murmur had long been audible over the whole of the right and unaffected side of the chest, towards the end murmur became audible over the heart itself, apparently as the result of cardiac muscle-failure, and consequent valve incompetence. It often, indeed, happens that towards the end of a case of intrathoracic tumour there is in the dyspnœa the element of cardiac muscle-failure, and the fact may possibly be utilised, in some small degree, as regards treatment. Pericardial effusion—dropsical or inflammatory—may take a share in

[1] Transactions of the Royal Medical and Chirurgical Society, vol. xxxi., p. 37.

the production of the dyspnœa of intrathoracic tumour, just as pleural effusion often does.

PULMONARY CHANGES RESULTING FROM INTRATHORACIC TUMOUR.



Before considering the percussion dulness of the side, that is so apt to be developed in the course of intrathoracic tumour, it will be well to have regard to changes in the lung resonance that may precede dulness.

Changes in Lung Resonance.

My predecessor in office, Dr. G. Newton Pitt, called special attention to a very peculiar condition of lung that may arise from *partial* bronchial obstruction, whereby it becomes over-distended, as it were, with air. While respiration is active the air under the circumstances, as Dr. Pitt states, "has greater difficulty in escaping than it had in entering, and the lung becomes over distended. The pressure may be so much raised that the diaphragm may be displaced two inches and the heart pushed out of position." If the whole lung be affected, its main bronchus being compressed or otherwise obstructed, the condition may be confused with pneumothorax, though in the latter case an X ray representation indicates the collapsed lung absent in the former. Dr. Pitt no doubt rightly, regarded this condition as usually persisting only for a time, inasmuch as through increase of the obstruction continued ingress of air becomes impossible and the imprisoned air is absorbed, dulness finally replacing the abnormal increase of resonance in question. We are under obligation to Dr. Pitt for directing attention to the subject. On first consideration, such increase of resonance as has been referred to may seem opposed to Skoda's dictum: "That the lungs partially deprived of air should yield a tympanitic, and when the quantity of air in them is increased a non-tympanitic, sound appears opposed to the laws of physics. The fact, however, is certain."

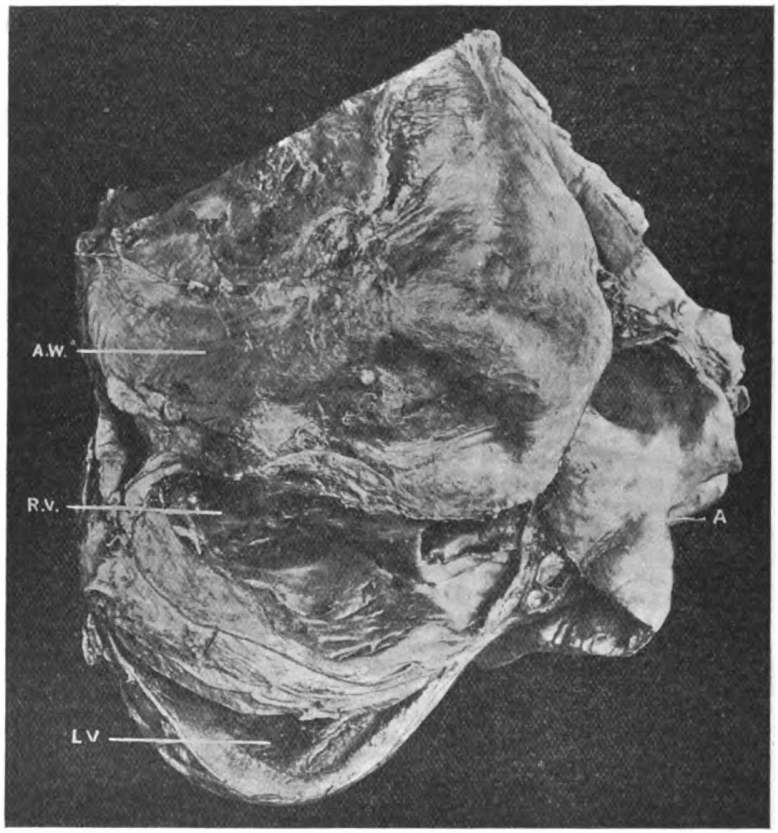
In corroboration of Skoda's statement Dr. Walshe remarked in his classic work: "Skoda is unquestionably right as regards the matter of fact, provided the word (tympanitic) be understood to mean 'tubular' or 'amphoric.'" But these are the only varieties of tympanitic resonance commonly met with over the lungs in disease, inasmuch as the abnormal air-containing space is not large, the "tubular" variety implying a smaller such space than the "amphoric." There is, moreover, no hard-and-fast line between them, as Walshe fully admitted. The essential thing is that *tympanitic quality* should be recognised, and whether we give to the resonance the name of "tubular" or "amphoric" will depend simply on the volume of air percussed. A still fuller tympanitic resonance such as, indeed, is seldom met with over the lung

FIG. 1.

From a case of endothelioma of the pleura. The illustration shows the internal surface of the parietal pleura. The pleura is very much thickened and shows many nodules, some of them as large as cherries.

is best described simply as a "full tympanitic resonance," but all three varieties possess tympanitic quality and vary only in "fulness" of resonance or volume of sound.

Let us take a healthy lung removed from the body and percuss it; it yields not the "non-tympanitic" resonance it yielded in the unopened chest, but "tympanitic" resonance, and to restore non-tympanitic resonance, such as the lung yielded in the unopened chest, what have we to do? Restore its tension by blowing it up with bellows attached to its bronchus.



There is no more familiar example of *acquisition by lung resonance of tympanitic quality* than the so-called "tubular" percussion sound above a copious pleural effusion, but the consolidating process of pneumonia offers many examples. I would urge the clinical importance of the recognition of tympanitic quality in lung resonance under abnormal circumstances, and at the bedside students, as a rule, I think, find no difficulty in distinguishing between "non-tympanitic" and "tympanitic" resonance, whether the latter be "full" or "empty," to use Skoda's most useful classification. The assumption of tympanitic quality by the lung resonance—such as it is—will often be observed in the course of intrathoracic tumour, and the principles I have referred to will generally enable its correct interpretation to be made.

That there is a very natural tendency to confuse excessive degrees of "non-tympanitic" resonance with "tympanitic" resonance is admitted, but the distinction can be made. I have often remarked upon Dr. Walshe's accuracy of statement (though he was an opponent of Skoda's teaching) displayed in his definition of simple excess of pulmonary resonance when he used the words in his description of the "quality" of resonance in emphysema—"more or less *approaching* tympanitic."

It may be permissible here briefly to refer to a remarkable occurrence associated with excess of air in the chest outside the lungs and due to a mediastinal tumour composed of tuberculous lymphatic glands. The late Dr. Joseph Coats, of Glasgow, related the following example. An infant, not known to be ill, suddenly developed dyspnœa and subcutaneous emphysema and died in 18 hours. Post mortem the anterior mediastinum was greatly blown up with air. The left lung was greatly distended with interstitial emphysema. The lymphatic glands at its root were tuberculous and there was limited tuberculosis of an adjoining portion of lung. An adherent gland had discharged its contents into the bronchus connected with this tuberculous piece of lung. "An irregular aperture ..... was found in the wall of one of the smaller primary branches of the main bronchus. This aperture led into a cavity in the gland and had allowed the softened contents of the gland to escape and infect the lung and finally the air to escape from the lung to the tissues outside." The case at least illustrates how far-reaching may be the effects of a mediastinal tumour on the respiratory system, though in the adult tuberculous lymphatic glands seldom form a "mediastinal tumour" with its usual clinical phenomena.

Excessive non-tympanitic resonance and the change from the normal non-tympanitic to tympanitic resonance of varying degrees of fulness over the chest form interesting features in the clinical manifestation of mediastinal tumour —aneurysm or neoplasm. Their explanation, of course, is the change brought about in the air-content of the lung and in the tension of its structure. Dr. Frederick Roberts in his monograph in Allbutt and Rolleston's "System," Vol. V.,

FIG. 2.

Oval saccular aneurysm of the ascending aorta, the size of a cocoanut. It is adherent to and incorporated with the wall of the right ventricle. Adhesive pericarditis is well seen. A.W., Anterior wall of aneurysm. R.V., Right ventricle. L.V., Left ventricle. A., Aorta.

p. 647, goes so far as to state "that a growth may interfere with the trachea only to such a degree as to cause accumulation of air and consequent distension of both lungs." Such change, however, is, as a rule, unilateral or local.

The distinction between the percussion resonance of lung over-distended with air—that is, with a *plus* content of air—and of lung with a *minus* content of air is, I believe, of extreme importance clinically, and in conclusion of the subject I would remind you once more of the dictum of Skoda: "A healthy lung strongly inflated within the thorax so as to be made to press against its walls gives a full, clear, but non-tympanitic sound (on percussion) over every part where it comes in contact with the walls."

Causes of Dulness.

The causes of dulness over the lung area, as a result of intrathoracic tumour, are numerous, and are apt to occur in combination. The tumour itself may be the direct cause, and enormous tumours are on record, almost sufficient in themselves to account for the dulness of the whole side; but here we are concerned chiefly with those causes that depend on secondary pleural and lung changes. Pleural effusion we have noticed to be a very common result, and Dr. Pitt has shown it to be much more common in the case of neoplasm than in that of aneurysm. The pleura itself may be the seat of new growth, and I have brought a specimen which shows the pleura covered with tumours, though not one could be said directly to be the cause of pressure symptoms. (Fig. 1.)

The patient was an engine driver, aged 58 years, who had fallen down while on his engine and injured his right side and right knee in December, 1908, and who died on April 30th, 1909. The right knee had been injured 13 years before and again later. It showed marked thickening of bone with blurring of outlines resembling an osteo-arthritis when the patient came under observation on March 8th, 1909. On the 23rd he was admitted to the medical wards and the prominent feature of his case was a copious hæmorrhagic right pleural effusion which, after tapping, rapidly reaccumulated, while there was only slight and irregular pyrexia. On April 29th there was found in the fluid a small fragment of tissue composed of large round cells and very probably a fragment of growth as stated by Dr. Loveday, superintendent of the clinical laboratory. I need not refer in detail to the remarkable appearance of the pleural surfaces on the right side, as it can be seen in the specimen I show, and is well seen in the photographs thereof. In one place the right lung below its hilus was invaded by a growth of the size of a plum. Microscopically the growth in the pleura was found to be endothelioma, though "in places it bore resemblance to a round-celled sarcoma." The growth in the joint had "a similar structure." It was "packed with large round cells and practically devoid of stroma." It may seem straining a point to bring this case under the heading of "intrathoracic tumours," though certainly such were present in abundance. Dr. Samuel West's important observations on the adhesiveness, if I may so say, of the pleural surfaces are too well known to require more than mention, but looking at this pleura, the site of almost universal malignant disease, one can hardly avoid thinking of the influence that such disease would be likely to exert upon this remarkable property of the pleural surfaces had there been no fluid to separate them. The pleura may be so thickened by new growth as itself to contribute materially to the dulness of the side present.

In the briefest possible manner I would refer to another of the specimens I have brought and have had photographed, in which the pericardium presented a pseudo-cystic tumour formed by a localised collection of purulent fluid. In a third specimen the pericardium itself is the seat of new growth.

Pulmonary Changes Associated with Dulness.

The pulmonary changes associated with dulness on percussion, as a result of intrathoracic neoplasms and aneurysms, were so thoroughly considered by Dr. Pitt last year that it will be unnecessary again to consider them in detail. I will merely briefly recall Dr. Pitt's statements that: (1) the lung may become collapsed and therefore solid; (2) there may be a so-called "retention pneumonia," the alveoli being filled with catarrhal cells while giant cells, apart from tubercle bacilli, appear (when there is first collapse and the alveolar walls remain long in contact organisation with obliteration takes place and new connective tissue is formed; further there may be a general fibrosis of the lung beyond the obstruction and a bronchiectasis); (3) dilatation of the bronchial tubes which are generally full of secretion; (4) fibroid thickening of the lung; (5) secondary infections resulting in breaking down of the lung, and (6) the still more destructive process of gangrene; and (7) from such processes as the last two, pleurisy and empyema may result.

These lung changes, however, are too often apt to be of little interest as regards auscultation, inasmuch as the bronchus of supply becomes blocked, and the glottic breath sound cannot be transmitted, while, of course, there can be no play of the lung structure. Vocal fremitus and resonance are likewise apt to be annulled. The heart sounds may, however, it would seem, be well transmitted in the neighbourhood of the heart. In the rare event of a tumour mass becoming broken down into a cavity, communicating with the glottis through an unobstructed bronchus, there may possibly be bronchial breath sound audible on auscultation, and certainly there may be cracked-pot sound on percussion. In a case which I published in THE LANCET in 1888,[2] while the latter physical sign was present, the breath sound could only be called "indeterminate."

IMPLICATION OF NERVE-SUPPLY TO THE LARYNX.

In the clinical recognition of intrathoracic tumour the interference with the innervation of the muscles of the larynx that such tumour may cause has been a matter of great importance to the physician ever since the invention of the laryngoscope made examination of the movements of the vocal cords and associated parts feasible. Although it is in the case of aneurysmal tumours that implication of the vagus nerve, and especially of the left recurrent branch, is most commonly met with, aneurysmal tumours have by no means a monopoly in this respect, and I am disposed to think paresis or paralysis of a vocal cord due to intrathoracic neoplasm is more common than it is generally believed to be. As regards the recurrent branch of the vagi, that of the right side hardly enters into our consideration to-day, inasmuch as it lies practically outside the mediastinum. An innominate aneurysm may, however, so extend upwards as to involve the right subclavian artery in such a way as to exert pressure upon the nerve, or, associated with aneurysm of the arch, there may be an independent aneurysm of the subclavian or of the innominate artery involving the subclavian. The frequency of the existence of more than one aneurysm in the same individual is well known. Less rarely the right recurrent nerve is caught as it were in malignant disease of the œsophagus; but for this to happen such disease must be situated so high up as to lie in the root of the neck rather than in the thorax. Goitre may, again, cause pressure on one or both recurrents, at the same time extending behind the manubrium sterni and so becoming an intrathoracic tumour.

Then there is the interesting question, raised by the late Sir George Johnson, as to the possibility of pressure exerted upon the trunk of one vagus causing interference with the bilaterally associated nuclei of the nerves in the direction of inhibition and resulting in paralysis of both vocal cords—proof of such occurrence does not seem to have been obtained, and it would seem always more likely in a case of double recurrent nerve palsy that some accidental and independent pressure had been directly exerted upon the right nerve as well as upon the left, as, for instance, by an enlarged lymphatic gland in malignant disease, by thickening of the right pleura about the apex of the lung, or by a small independent aneurysm involving the subclavian in the case of intrathoracic aneurysm.

But the interest of bilateral palsy of the vocal cord does not end here; there comes in the question of the relative predominance of the adductor and abductor muscles respectively of the vocal cords—a matter of great clinical importance. It is now a well founded belief that the abductors are the muscles to be first weakened under paralysing influence. The fact has little importance, perhaps, when the affection is of one vocal cord only, but it is quite otherwise when there is bilateral paresis or paralysis of the abductors, permitting the adductors to close the glottis without any pronounced degree of spasm and simply by lack of the opposition which the abductors should supply under normal circumstances.

[2] THE LANCET, Oct. 27th, 1888, p. 809.

Another consideration, which I do not think has received all the attention it deserves and which was the subject of a thesis in 1865 by Professor Wyllie of Edinburgh University, relates to the concavity of the upper surfaces of the true vocal cords, whereby the edges of the cords may be forced into apposition and, in valve-fashion, the glottis be closed by the *in-rush* of air, especially when the current is forcible and the glottis small and narrow. Physiologists have long known that this valve action of the vocal cords is specially demonstrable in the case of young animals whose recurrents have been cut. Granted any weakness of abduction of the cords, the predominance of adduction will in all probability be rendered more dangerous by this valve action to which Wyllie called attention.

Sir George Johnson in 1875, with reference to a case described by him, remarked: "Looking into (the) larynx with the mirror, I saw the vocal cords of their natural colour nearly touching each other in the middle line and nearly motionless. ..... During inspiration the glottis did not expand as in the normal state, but, on the contrary, the cords appeared to be pressed nearer together by the inspiratory current of air, while in expiration again the cords were slightly pushed apart by the outgoing stream of air."

The greater the dyspnœa the more forcible will be inspiration, and consequently the greater this tendency of the true cords to act in valve fashion in this dangerous manner. The condition in which the abductors of both cords are weak is all the more likely to be overlooked without the laryngoscope, inasmuch as the voice is unaffected, and in quiet breathing there may be little or no stridor, although on any exertion and in sleep inspiratory stridor is usually pronounced. When there is direct pressure of an intrathoracic tumour, especially aneurysmal, upon the trachea, the stridor, as already noted, is usually double, though the inspiratory sound is the better developed as a rule. An interesting clinical point concerning the site of obvious obstruction—in the trachea or at the glottis respectively—is, in the latter case, the so-called excursion of the larynx downwards with inspiration and its return in expiration. While palsy of one cord may affect the voice little or hardly at all, direct pressure of a tumour or aneurysm on the lower part of the trachea may interfere to some extent with and diminish its tone, the clang of the cough being usually exaggerated in both cases.

Lastly, the two conditions, palsy of laryngeal muscles and direct pressure upon the trachea, are quite compatible in the same case. As regards the clinical diagnosis of one palsied cord, this can be reliably accomplished only by means of the laryngoscope, inasmuch as the degree of interference with the voice and the presence of stridor on forcible inspiration seem to vary a good deal in different cases.

With the production of adduction resulting from nerve-irritability and spasm there will again come into play what may be called the valve action of the vocal cords, and the greater will be the predisposition to this effect the more forcible is the inrush of air, as in dyspnœa. A very slight degree of spasm of the adductors, the result of nerve irritability, may then determine a very dangerous degree of closure of the glottis. To such result, however, spasm may contribute only by bringing the cords within the range of their dangerous mechanical valve action.

AFFECTION OF THE SYMPATHETIC NERVE.

Both in intrathoracic aneurysmal and neoplasmic tumour the cervical sympathetic nerves may be implicated, affection of the pupil, palpebral fissure, and sweat secretion resulting. The tumour must, of course, extend upwards high enough to involve the sympathetic fibres, leaving the cord by the first and second dorsal roots to ascend in the sympathetic chain, and it must extend in the backward direction. As Gairdner stated: "Intrathoracic aneurysm to affect the sympathetic may be expected to arise from the upper and back part of the arch ..... or its primary branches, the sac projecting backwards in the direction of the sympathetic trunk or its ganglia and of their communications with the spinal system." Before he published a case of the kind in 1855, Dr. MacDonnell, of Montreal, had called attention to a case of malignant tumour producing pressure on the sympathetic in connexion with contracted pupil and ptosis on the affected side. The usual affection is paralysis, with the familiar contracted pupil, diminished palpebral fissure, and interference with sweating on the affected side of the head and neck, though the opposite effects may result, it is believed, from irritation of the nerve. Dr. Purves Stewart has shown how well the area of skin rendered sweatless may be mapped out by dusting charcoal over the head and neck. After general sweating has been induced by pilocarpine the charcoal adheres to the normal sweating side, while it is easily blown off the dry side. Doubt has been recently thrown upon the exclusive causation of unequal pupils in the manner stated, and there has been supposed to exist a relationship between the state of the pupils and of the arteries—"with low blood pressure in one carotid the pupil on that side is dilated, with high pressure contracted." The various other causes of unequal pupils that may accidentally and independently coexist with intrathoracic tumour must, of course, be given due consideration in the investigation of a case before the symptom be admitted to have weight in evidence.

NERVE PRESSURE.

Affection of the brachial plexus, causing weakness and sensory disturbance of the arm, is often included among the symptoms of intrathoracic tumours, especially aneurysmal, but it is obvious that the tumour whatever its nature must extend high up in order to produce the symptom. The affection of the arm in true angina pectoris, with implication of the coronary orifices, must not be confused with that just referred to.

PARAPLEGIA.

One of the rarest clinical manifestations of an aneurysm of the descending aorta is paraplegia. When again the spinal column is invaded by malignant growth, secondary to like mediastinal growth, the same symptom may be developed. It was quite suddenly developed in the case of an aneurysm I witnessed during my hospital residence, the patient, while I was going round the ward, calling out with intense pain in his back and rapidly becoming paraplegic. Secondary malignant growth in the spine is a much less rare cause of paraplegia than aneurysm.

DYSPHAGIA.

It is a familiar fact that dysphagia may be a merely transitory and little pronounced symptom in cases of intrathoracic aneurysm, when the position of the aneurysm, in relation with the gullet, would seem to indicate a good deal of interference with the function of the latter. Moreover, the patient may never have been conscious of such interference under like circumstances. It is a good rule of practice to be careful in passing a bougie for dysphagia, lest the cause of the dysphagia should be an aneurysm.

In malignant tumour of the gullet dysphagia is, of course, an all-important symptom, and the possible implication of the recurrent laryngeal nerves in the growth has to be borne in mind with regard to the larynx.

HÆMORRHAGE.

Prolonged repeated slight hæmoptysis has long been recognised as significant of intrathoracic growth involving the lung. The late Sir William Gairdner, again, called attention to the oozings of blood that may result from an intrathoracic aneurysm. The important fact, in our present consideration, is that slight hæmoptysis may occur over a considerable period of time in the course of intrathoracic tumour—neoplasm or aneurysm. Such slight hæmoptysis, as the result of aneurysm, seems to be, as a rule, short and not much over a month in duration. It is curious to note, however, that a much more profuse single hæmorrhage may be survived for years. Sir William Gairdner related a case in which a profuse hæmoptysis occurred nearly five years before the death of the patient. For several years after the first hæmorrhage the patient "continued occasionally to bring up a more or less tinged expectoration—sometimes rusty, sometimes purple, almost never of anything approaching pure blood." At last this patient died after the sudden loss of 8 or 10 ounces of blood which suffocated him. Post-mortem examination revealed a very large aneurysm of the descending aorta "adherent over a considerable space to the left lung and opening freely into the lung and bronchus and trachea. ..... The left bronchus was stretched over the sac and had its posterior wall absorbed throughout its whole length. ..... The sac was filled with firm coagulum" to which no doubt the patient owed the prolongation of his life.

It may be said that hæmoptysis is often a late symptom in aneurysm and an early and frequently a persistent one in neoplasm. In one of my own cases of tumour the patient

attended the out-patient department of the infirmary for a slight hæmoptysis, which in the absence of definite physical signs was naturally regarded as probably of tuberculous origin. To increase the resemblance of the case to a tuberculous one, a large tumour mass was ultimately formed at the upper part of the right lung and actually became excavated, but there was fulness in the infraclavicular region, not the usual depression of the tuberculous process.

Hæmorrhage from Complicating Pulmonary Tuberculosis.

When we consider the great frequency of tuberculosis in general, it is not surprising that the disease should be found occasionally complicating intrathoracic tumours—neoplasmic or aneursymal. The affection may be old and obsolete. On the other hand, I have found it active miliary and the cause of pyrexia in a case of aneurysm. It is obvious, therefore, that hæmoptysis may be caused by tubercle, though an aneurysm be present. Rarely, again, hæmoptysis may proceed from lung tissue directly invaded by, and incorporated with, an aneurysmal sac, without the integrity of the wall of the latter being compromised. On the other hand, without any tuberculosis or direct implication of the lung by the aneurysm, blood from the sac may be aspirated into the lung structure, as pictured by Gairdner in his "Clinical Medicine," pp. 482-3.

Hæmatemesis.

Hæmorrhage into the gullet, usually soon, if not immediately, fatal is, of course, a well-known accident of intrathoracic aneurysm affecting the descending part of the arch. However confidently the diagnosis of intrathoracic growth had been previously made it would be a singular trial of one's faith in it, if the case terminated suddenly by a profuse hæmatemesis, and yet this practically happened in a case reported by the late Dr. Lindsay Steven.[3] That the blood did not appear externally is nothing to the point. The patient, aged 57, had suffered from dysphagia, which began in December, 1889. A No. 16 œsophageal bougie passed 13 inches and was then arrested. The diagnosis of cancer of the gullet was made, and on April 1st, 1890, Dr. Steven recorded that he was "quite satisfied that the case was one of cancer of the œsophagus." A great improvement in swallowing and consequent increase of the patient's weight, however, occurred. Dr. Steven was naturally led to doubt the accuracy of his first diagnosis and consider whether or not the dysphagia "might not be due to the presence of an aneurysm or solid tumour at the bifurcation of the trachea." In October he had the "gravest suspicion of aneurysm at the bifurcation of the trachea." On the 18th the patient spat up a small quantity of dark blood, and for the first time complained of pain in the chest. He died suddenly on the 29th, having "raised himself in bed suddenly because of some distress referred to the chest," and then sank back and speedily died with indications of internal hæmorrhage. At the post-mortem examination, on laying open the thoracic aorta (removed from the body) from below upwards "a circular opening with thin and somewhat ragged edges [was] found," which led "into a ragged cavity." On laying open the gullet "at the level of the obstruction ..... a large rugged ulcerated cavity ..... was found in its wall." The upper margin of this excavation was raised and rather sharp and presented the typical characters of the margin of a malignant ulcer. "The stomach [was] greatly distended, being filled with red blood. ..... The duodenum and several feet of the upper part of the small intestine were similarly distended."[4]

Cutaneous Hæmorrhage.

Cutaneous hæmorrhages in the form of petechiæ or ecchymoses may be only expressions of a general hæmorrhagic diathesis in the most malignant sarcomatous growths of the mediastinum, while, in the same case, hæmoptysis, and other hæmorrhages from within, may result from the same cause. On the other hand, the sac of an aneurysm (generally of the arch) coming forwards may be the source of actual cutaneous hæmorrhage. At first there is usually only blood-staining of the skin, but a local inflammatory condition is often set up, with redness and tenderness, so that, as in a well-known case, the patient may regard the red, tender, and possibly elevated spot as a "boil." The deposition of fibrin in layers is the great preventive of rupture externally as in other directions, and even when hæmorrhage does occur it is often, as Gairdner said, "a mere oozing or succession of oozings filtered through these obstructions." On the other hand, as I have seen, the issuing stream of blood may spout up a considerable distance above the surface of the chest of the recumbent patient. In a case I witnessed, as a hospital resident, the patient survived the rupture many days. Dr. Walshe recorded a case, indeed, in which the patient "must have lived for nearly two months with a gradually increasing extent of his chest wall and aorta replaced by lint."

PHYSICAL METHODS OF DIAGNOSIS.

Inspection.

It will often happen in cases of intrathoracic tumour and aneurysm that the mere inspection of the chests puts the observer almost at once in possession of the diagnosis. It is customary in chest diseases to limit the application of inspection, regarded as a physical method of diagnosis, to the thorax itself, but, specially in the case of intrathoracic neoplasm, it is better to include all that may be obvious to the observer possessing a bearing on the diagnosis under consideration. Thus enlargement of the lymphatic glands above and below the clavicle or in the axilla may afford valuable evidence of malignant growth within the thorax. The significance of external tumour on the thorax, either from projection of an internal one, or of a superficial and essentially parietal one, requires little comment, care o course being taken to exclude superficial tumours, that have existed for many years and clearly have nothing to do with recent developments. Significant tumours in our present consideration have usually appeared recently, or there may be the scar of a surgically-removed tumour.

Intrathoracic aneurysms frequently form local projections, neoplasms less often, and in the latter case independent growth in the chest wall has to be distinguished from projection of internal growth. In the case of aneurysm the seat of projection is usually, as might be expected, the upper part of the thorax often involving the middle line in some degree and extending more frequently to the right than to the left of it. But the projection may be altogether to the right of the sternum and extend under the nipple itself, encroaching on the situation of a distended right auricle, or in rare cases of aneurysm of the descending aorta, it may be situated to the left of the spinal column. In almost all cases careful inspection over its surface will reveal pulsation, though it is astonishing how easily pulsation may escape observation when there is no projection of an aneurysm. This year only I regarded a dull area as due to intrathoracic growth because I, and those associated with me, failed to observe pulsation carefully looked for. A few days later a somewhat accentuated aortic second sound and diminution of a radial pulse were allowed more weight than at first in the diagnosis, which was changed to that of aneurysm. The patient proved absolutely intolerant of iodide of potassium, which produced quite grave symptoms, and he died in a short time. Post-mortem examination revealed a large aneurysm. Why visible pulsation was absent in this case, overlooked if you will, is a mystery to me to this day. The only explanations I can offer are: that there was much deposition of clot in the sac, and that the heart was evidently greatly depressed, which probably accounted also, to some extent, for the ill-development of accentuation of the second sound, that, along with the absence of pulsation, at first led to the erroneous idea that neoplasm rather than aneurysm existed.

The distended, enlarged, often tortuous, veins coursing over the thorax and obvious in the neck and arms form a conspicuous feature of many cases of mediastinal tumour and aneurysm. This condition is again often associated with œdema of the face, upper thorax, and arms which may reach an extreme degree. It is commonly held, I think, that such a condition is more frequently present in the case of neoplasm than in that of aneurysm, a statement with which I cannot quite agree. At any rate, I have seen most pronounced examples of the condition in aneurysm, one case in a lad of 20. Enlarged veins in a lesser degree may course over the abdomen, the circulation within them passing downward to the tributaries of the inferior vena cava.

Inspection again may indicate important disturbance of lung functions, especially immobility more or less of one side, expansion being always more affected than elevation during inspiration. A difference between the two sides—

unilateral change—is often much more obvious to the eye as regards movement than as regards mere shape. For instance, it is a familiar fact that the changes in the contour of the chest produced by copious effusion into a pleura are bilateral rather than unilateral, though difference between the movements of the two sides is marked and obvious.

With unilateral *retraction* of the chest as the result of intrathoracic tumour there will generally go excessive play of the unaffected side. Complete obstruction of the main bronchus is probably in most cases the predominant factor in the production of unilateral retraction, though the retraction may be more apparent than real owing to the abnormal activity of the sound side.

"Tracheal tugging" is usually regarded as a palpation sign of aneurysm, but the diagnostic value of the sign is much enhanced when the movement of the larynx is so pronounced as to be visible and therefore to become an inspection sign. When this happens there is probably always aneurysm present.

Palpation.

One of the specimens I have brought with me shows a most unusual condition, and one, I may say, therefore peculiarly difficult of diagnosis. I have not been able to find a similar case recorded, though Sir William Osler makes reference to such an one in his article on Aneurysm in Allbutt and Rolleston's "System of Medicine," vol. vi., p. 658—a case of Dr. Gee's. During life in my patient there seemed to be two apex beats—if I may so say—one including and not extending much beyond the normal apex situation and the other quite separate and approaching the left mid-axillary line. Moreover, the whole heart seemed to be thrust forwards in systole, much as it is when a solid mass or an aneurysm lies behind the heart and between it and the spine. This led me to think that there was an aneurysm of the descending aorta behind the heart, causing the heart to be thrust forwards in each systole, though there was always, in this view, the difficulty of explaining the absence of pulsation between the spine and the more external of the two impulses. The curious fact was ascertained by examination post mortem that an aneurysm *in front of* the heart can occasion a pulsation closely resembling that of an aneurysm or neoplasm situated *behind* the heart, so much so indeed as to cause clinically confusion between two opposite conditions. About the same time, curiously, I had in the wards a closely similar case. Although a necropsy was made, it was made on condition that no part of the body should be removed.

The peculiar thrusting forwards of the heart in systole that occurs even when a solid tumour is situated *behind* the heart, no doubt depends on the ventricles of the heart becoming a solid mass of rigid muscle in systole, which mass thrusts itself between the spine and the sternum, with its adjoining cartilages. The spine cannot yield backwards, therefore the sternum has to yield forwards. What may be called the special impulses of the heart are quite lost in a *general* heave forwards. No doubt the instruments of precision we now possess may distinguish a dual pulsation in the case of an aneurysm situated behind the heart, but my old-fashioned ideas make me apprehensive of such blending of the two impulses in the case I refer to as would make their distinction one of peculiar difficulty. Of one thing I am convinced; it is: that to the eye, at any rate, the two very different conditions—a solid tumour and a large aneurysmal sac behind the heart—occasion to the clinical observer a very similar condition, while I doubt if the most sensitive hand could convey the double impulse that must, one would think theoretically, be present in front in the case of aneurysm of the descending thoracic aorta.

A valuable sign of intrathoracic aneurysm that has its place under palpation is the diastolic shock, representing the closure of the semilunar valves, that may be felt over a superficial aneurysmal sac. This shock, no doubt, is the palpation-sign corresponding to the peculiarly valuable auscultatory sign of accentuation of the second sound, to be considered under auscultation. Thrills too, generally systolic, rarely double and possibly diastolic only, felt under like circumstances come better under the discussion of auscultatory signs, with the murmurs, to which indeed they for the most part correspond. That neoplasmic tumours may occasionally pulsate seems to be unquestionable, and the fact that the large arteries are often found post mortem undiminished in calibre, though surrounded by new growth, is noteworthy.

ARTERIAL EFFECTS OF ANEURYSM.

In the distinction between aneurysm and neoplasm within the thorax, evidence from the condition of the arteries beyond the tumour may prove of great value. A difference between the radials, for instance, is a familiar sign of aneurysm of the aorta, though the interference with the affected radial may be brought about in different ways, certainly not always by the interposition of an elastic sac between the heart and the artery examined. Sir William Osler records a case in which there was "no trace of pulsation and not the slightest throbbing in the abdominal aorta or in the peripheral arteries of the leg." The patient "had a very large area of pulsation in the left scapular region" and presumably an aneurysm of the descending aorta. Dr. Fagge described "a case once in Guy's Hospital in which the pulses at the wrists became quite imperceptible." I had myself a similar case. In such cases the warmth and vascularity of the pulseless limbs are well maintained.

Although Stokes referred to the "subclavian or carotid arteries" becoming "obliterated" as a result of malignant growth within the thorax, it is a pathological fact already considered, that the large arteries may maintain their calibre in the very centre of a neoplasmic mass. I think it may be granted that interference with peripheral arteries, in weighing evidence between aneurysmal and neoplasmic intrathoracic tumours, must go to the side of the former.

So called "tracheal tugging" has been already referred to as an inspection sign of aneurysmal tumour of the arch, but it was originally described as a palpation one. The difficulty with regard to it is that with the finger and thumb applied to the lower border of the cricoid cartilage, an impulse, distinct enough to count the pulse-rate by, may be felt in cases in which there is only some amount of dilatation of the arch and no true aneurysm. By making this sign an inspection one we get rid of its minor developments, which are of doubtful import and may only lead us into error.

PERCUSSION.

I have discussed at such length the percussion changes concerning the lungs which arise in the thorax as a result of intrathoracic tumour, that I must be brief here and speak only of such dull areas as the tumour (neoplasmic or aneurysmal) itself may occasion. The most typical area of dulness may be designated a "mediastinal dulness" and is situated at the level of the manubrium sterni and characterised by its *crossing the median line and reaching to neither costo-acromial angle.* Such dull area may or may not be united to the cardiac dulness by a neck of varying breadth and length, and it may barely cross the median line on one side while extending for a considerable distance on the other side. The lower border of a mediastinal dull area is usually convex downwards, whether or not there be a neck uniting it with the cardiac dulness. An aneurysmal sac is specially apt to extend to the right of the sternum, while such a sac springing from the transverse part of the arch may get to the left of the bone, and the more so the further from the valves it has its origin, but the less likely, on the other hand, is it then to displace the lung and reach the surface. An aneurysmal sac low down to the right of the sternum may cause a dull area entirely to the right of the sternum, lower down but at a varying level. It rarely happens that an aneurysmal sac *per se* causes a dull area behind, to the left side of the spine. In the case of neoplasm I have found such an area only when the ribs themselves were the seat of growth. The lungs may in that case escape involvement, and the parietal growth may not acquire such thickness as to annul the lung resonance.

AUSCULTATION.

There is, I think, a curiously widely spread belief that murmur is almost invariable, at least very common, over aneurysmal tumour. This is, of course, very far from being the case. Directing our attention to the physiological sounds of the heart first of all, their departure from the normal is often in the opposite direction, so that a frequent combination indeed is a practically absent first sound and an extremely loud second sound. During systole the auscultator is aware rather of an impulse—jog or push—than of sound—murmur or sound in the technical sense; of such valuable impression I presume the fashionable double or flexible stethoscope of to-day can give no indication.

In many of the cases referred to in which the first sound is indubitably absent, systolic murmur is present, though very feeble and short. The second sound, on the contrary, is of great loudness and intensity—and as we have found on palpation the hand often receives a corresponding shock. The late Dr. James Warburton Begbie called special attention to this sign of aneurysm in 1863 in a paper which Sir Dyce Duckworth has preserved for us in his Sydenham Society "Memoirs" of Begbie.

We know that there are minor degrees of accentuation of the aortic second sound commonly met with, over simply dilated aortas, and, as so often happens with regard to clinical signs, it is sometimes hard to draw the line between such accentuations and that which denotes aneurysm to the practised observer. The impression given to me by the true aneurysmal-accentuation is that of *extreme tension of the valves*, the result of the greatest force, indeed, that could be borne without actual rupture of their structure. I have no hesitation in giving such accentuation the first place among the auscultatory signs of intrathoracic aneurysm involving the ascending arch.

An interesting diagnostic point is the absence of this sign in aneurysms of the arch *that do not involve the ascending part*. An aneurysm of the posterior part of the arch separated from the valves by a non-dilated portion does not produce this sign, but it will be obvious how likely it is that the commencement of the aorta, being atheromatous, will be dilated, and, as a result, there will be a minor degree of accentuation of the aortic second sound. I have already referred to two cases having as the chief symptom paroxysms of dyspnœa, apparently not due to cardiac disease, in which the absence of accentuation of the aortic second sound seemed to negative aneurysm of the first part of the arch, the cases proving post mortem to be cases of aneurysm limited to the posterior part of the arch. The weak point of the sign, strong as it is when well developed, is the gradual transition from the *minor* accentuation of dilated aorta to the *major* accentuation of true saccular aneurysm.

Murmurs.

While I contend that the most valuable auscultatory sign of aneurysm is unquestionably accentuation of the aortic second sound, I admit, of course, that murmurs are very common. The most common murmur is the systolic, but such a murmur is of extremely frequent occurrence in many conditions other than aneurysm, and so its diagnostic value *per se* is small. Among its many causes, may be enumerated actual aortic stenosis, a dilated aorta with the orifice actually larger than normal, degrees of valve-change from slight general thickening to the marked projection of an inflammatory nodule or rigid valve, a thrombus attached to a diseased cusp, and so on. Diastolic murmur when present in aneurysm is often the merest appendage to a greatly accentuated second sound. Even when such a murmur is loud and well conducted down the sternum, the accentuated second sound may still remain to point to the nature of the disturbing process in the valve function—i.e., enlargement of the orifice, *not* diminution of the valve surface. Of cases of aneurysm, involving even the first part of the arch, it must be admitted that in a certain proportion the second sound has ceased, although the presumption is strong that at one time it had been not only present with the murmur that finally replaced it, but had been actually accentuated. In these cases there is extreme dilatation of the orifice, such as to render the valves incapable of so closing as to result in a sound.

In the case, again, of double murmur—even with accentuated second sound—the risk of overlooking aneurysm proper and regarding the case as one of simple dilated atheromatous aorta is considerable. Moreover, pathogically a dilated aorta and a diffuse aneurysm—so-called—run into one another. I draw the distinguishing line for practical purposes at the production of *pressure symptoms* in the case of true aneurysm. I have occasionally had confidence in the diagnosis of simple dilatation of the aorta strengthened by the carotids and subclavians retaining their characteristic exaggeration of pulsation, while in the case of aneurysm these vessels are apt to have their pulsation interfered with. As far as the double murmur of combined aortic *stenosis* and incompetence is concerned, *general* diminution of visible arterial pulsation is of value in diagnosis. Moreover, in its case the second sound tends towards diminution, *not* increase. Local causes, especially interference with the orifice of one or more of the large arteries by a patch of atheromatous disease, may, of course, likewise occasion diminution in pulsation of one or more of the great arteries of the neck.

As a general rule the statement may be accepted that a diastolic murmur audible over an aneurysm of the arch is evidence of incompetence of the valves, and an accompanying accentuation of the second sound is corroborative thereof. There is no incompatibility between accentuation of aortic second sound and diastolic murmur—rather should marked accentuation of the sound lead to careful seeking for the slight murmur that gives evidence of commencing leakage.

So much for the question of the auscultatory phenomena of aneurysmal intrathoracic tumours.

Murmur with Intrathoracic Tumour: Illustrative Case.

The presence of murmur has been regarded as a diagnostic point in favour of aneurysm rather than neoplasm. The rule may be accepted, but there is such an amount of exception that its value is greatly diminished. One of the best examples of murmur in a case of intrathoracic tumour I have met with may be related in some little detail, inasmuch as it illustrates other features of the disease, and I have not yet related a clinical case in any detail. It was the case of a married woman, aged 26, who, when admitted to the Manchester Royal Infirmary on July 17th, 1890, had been five months ill. Paroxysms of cough and slight hæmoptysis had been the early symptoms, curiously relieved after a miscarriage. Dyspnœa and cardiac palpitation soon, however, supervened, and she had a peculiar desire to vomit or retch with a large flow of saliva (a symptom I have recently met with in intrathoracic aneurysm also), "large quantities of clear neutral fluid" being brought up. Loss of weight and strength were progressive. There were no distended veins on the front of the chest. The whole heart seemed to be thrust forwards in systole. The left side of the chest was dull all over with the exception of a trace of resonance in the supraclavicular region. The intercostal depressions showed no levelling, and though the dulness was so extensive it did not transgress the middle line in front. The left side was immobile and vocal fremitus absent over it. There was practically respiratory silence on the left side. Over the right side there was vesicular breath sound with a few rhonchi. The heart sounds to the left of the sternum were at first normal, with the exception of accentuation of the second sound of the pulmonary artery. Over the sternum and the whole of the right side of the chest a loud systolic murmur was audible. There was no laryngeal palsy and the voice was clear. The pupils were normal. The urine was normal. Looseness of the bowels was a troublesome symptom. On July 22nd pain on the left side was complained of, and it continued more or less to the end. The temperature throughout was elevated, the fever being of remittent, irregular type. On Sept. 11th a systolic murmur became audible over the apex of the heart. On the 16th there was œdema of the feet, and the intercostal depressions on the left side were less marked. On the 22nd the intercostal depressions were becoming obliterated on the left side, while the dulness extended to the right border of the sternum, and pulsation was visible to the right of this bone. Profuse perspirations occurred, and the left side of the chest became expanded. A small quantity of pus was withdrawn from the left side of the chest. The patient died on Sept. 27th. Post mortem: The left side of the chest was expanded. The left pleural cavity was obliterated over the posterior two-thirds of the upper lobe and the posterior half of the lower lobe. The anterior and inferior portions of this pleura contained pus and blood-clot. Left lung consolidated, its lower lobe compressed. The visceral pleura showed apertures through which pus exuded. Lobes of lung adherent. Lung of firm consistence, grey colour, riddled with small, irregular cavities, with ragged walls and filled with pus. In the upper lobe near the hilus there was a mass of reddish-grey tissue continuous with a growth of the posterior mediastinum, the size of an orange, between the aorta behind and the right and left bronchi in front, and reaching as high as the lower end of the trachea and as low as the origin of the sixth intercostal artery. On the left side a process of tumour surrounded the left bronchus, the walls of which were formed of tumour

tissue: a No. 12 catheter passed through it. The growth extended half an inch to the right of the vertebral column. On section the growth was found of soft consistence and pale greyish-white colour with pink softer centre. The pericardium contained a large quantity of yellow fluid and flakes of lymph. Its upper posterior third showed nodular growth. Heart thin-walled and dilated. No valve disease. Microscopical examination showed the growth to be a lymphosarcoma.

Published reports of cases referred to in the lecture.—THE LANCET, Oct. 27th, 1888, Case of Excavated Tumour of the Lung. Medical Chronicle, December, 1890, Two Cases of Intrathoracic Tumour. Ibid., April, 1901, On a Sign of Intrathoracic Tumour involving the Posterior Mediastinum. THE LANCET, Feb. 17th, 1894, Clinical Lecture on a Case of Tumour of the Lung.

An Address
ON
SOME EARLY SIGNS AND SYMPTOMS IN NERVOUS DISEASE.

Delivered before the Harveian Society of London on Nov. 23rd, 1911,

BY JAMES TAYLOR, M.D. EDIN., F.R.C.P. LOND.,

PHYSICIAN TO THE NATIONAL HOSPITAL FOR PARALYSED AND EPILEPTIC, QUEEN-SQUARE, W.C., AND TO THE ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS; CONSULTING PHYSICIAN TO THE QUEEN'S HOSPITAL FOR CHILDREN.

GENTLEMEN,—I am desirous of bringing before you to-night certain difficulties which have confronted me in the course of practice in reference to the diagnosis of nervous disease. It is often exceedingly difficult to determine whether a patient whose case is submitted to one's judgment is suffering from real structural organic disease or is the victim of functional disorder. I am bound to say that with increasing experience I find that I am much less inclined to make a diagnosis of functional disorder than I was a few years ago, and no doubt one reason for this is the increased importance which we have learnt to attach to certain symptoms, and the discovery of the weight which ought to be given to certain physical signs, previously undiscovered or regarded as unimportant. Another difficulty that occurs is, after the real organic nature of the ailment is recognised, the determination of its nature. I am afraid that there is a tendency to regard "disseminated sclerosis" as the dumping ground into which neurologists are rather inclined to shoot everything that is indefinite but organic, and perhaps the cases I am about to relate may not help to remove the impression. Yet I think most neurologists are aware of this danger and are becoming more alive to the possibility of being able, sooner or later, to subdivide the cases which we regard as examples of this disease, and perhaps to classify some of them under a different heading.

DISSEMINATED SCLEROSIS.

I remember a few years ago a patient whose case was very instructive. She was brought to see me on account of some difficulty which she had recently experienced in walking quickly. She was a young good-looking girl, and as she walked across my room nothing very obvious was noticeable in her gait except perhaps a little difficulty in preventing the toes of one foot from catching the ground. Vision was good; there was no nystagmus, no diplopia, no difficulty in using the hands, no trouble with the sphincters. I may mention also that there was a history of "emotional disturbance," and I confess that I thought the case was a functional one. However, I refused to commit myself until I had made an examination of the patient in bed. I made this examination the next day and found that there was well-marked ankle clonus on the side on which I had detected a little peculiarity in the action of the foot, and there was distinct and unmistakeable extensor response from each sole. It was then obvious that the case was an organic one, and I may add that in a few months' time it was clear that it was in every respect a characteristic one of disseminated sclerosis.

SPINAL CARIES.

Spinal caries is also a condition to have in mind in reference to any patient complaining of difficulty in walking. I always remember a case which impressed me very much at the time—that of a young girl who was a nurse at a cottage hospital in the country. She complained of difficulty in walking and of difficulty in using her left hand. The condition was regarded as hysterical, and she was urged to go on with her work. She did so until it was no longer possible, and she was then admitted as a patient to Queen-square. There were marked weakness of the legs, exaggerated knee-jerks, and ankle clonus. It was before the importance of the plantar reflex was realised. There was no distinct impairment of sensation except in one arm. Both arms were very weak, and there was much thickening about the cervical spine. The girl rapidly became worse and died a few days after admission. There was extensive disease of the spinal column and pressure myelitis.

We all know how difficult it is to get away from a diagnosis once made. In this case the idea of hysteria had apparently dominated the minds of those who saw the patient in the early stage and had continued to do so even after signs were present which should have altered this view. Two points in such a case should be mentioned: 1. That cervical caries is not always easy of detection. No curvature is usually present, only thickening about the cervical spine. 2. That practically complete motor paralysis may be present in such a case without any marked change in sensation.

SUBACUTE COMBINED SCLEROSIS.

There is a disease which has been described within the last few years under the name of subacute combined sclerosis. An early sign in this disease may be a peculiarity in walking, which resembles somewhat the walk in tabes. Yet in many such cases examination shows that the knee-jerks are active—at least in the early stage—and the somewhat anomalous gait, combined, it may be, with what may be called a slightly hilarious frame of mind, may easily mislead one into thinking the condition a functional one. And with reference to the peculiar mental state occasionally present in this disease as well as in disseminated sclerosis, it should never be forgotten that not infrequently we have a combination of hysteria with organic disease—what someone has called a hysterical picture painted on an organic background. A case of which I have published full details elsewhere illustrates this. The patient was a woman aged 60, sent to me by Dr. J. Corbet Fletcher on account of difficulty in walking. She came into the room with a somewhat high-stepping, ataxic, spastic gait; she chattered and laughed about her walking, made light of it, and apparently looked upon it as a joke. She refused to take it seriously and submitted to examination somewhat deprecatingly. She looked pale and distinctly anæmic. She had exaggerated knee-jerks and ankle clonus, and in the course of a few weeks became worse and, at Dr. Fletcher's request, was admitted to Queen-square. She was recognisable as a sufferer from the disease when I saw her first; she presented the complete picture in a few weeks and the clinical course was quite characteristic. She died within six months of her first symptoms and her spinal cord showed the characteristic changes. Yet when I first saw her the condition was one which might easily have been regarded as functional, and only functional, but for the comparatively slight signs of structural change that were present.

TABES WITH GASTRIC CRISES.

A few years ago I was consulted by a tall, well-built man, the brother of a nurse whom I knew, on account of two or three recent attacks of sickness. He described them as "bilious attacks." They came on quite suddenly, usually in the night, and the sickness persisted for several days. There was no severe abdominal pain, except in the paroxysm of vomiting, and the attack passed off without leaving anything but some weakness behind. There was no headache, and migraine, which at first occurred to me, was excluded. On examination, however, I noticed that he had small pupils, and these I found were inactive to light. There was no impairment of vision. His knee-jerks could not be obtained, and he had occasional shooting pains. There was no ataxy. It was then, of course, evident that one had to deal with a case of tabes with gastric crises, and the subsequent progress of the case—difficulty in walking, Charcot's disease of the ankle, and perforating ulcers of the big toes—confirmed the

diagnosis. In my experience cases of tabes with gastric crises are rarely ataxic, and not infrequently the gastric crises cease to recur, and the patient, although often broken down in health, is not necessarily the victim of a progressive disease. The patient whose case I have described is now, after 18 years, alive, and only to be recognised as a tabetic on very careful examination. Yet but for the presence of the Argyll Robertson pupils and the absent knee-jerks in the early stage, the true nature of the disease might easily have escaped notice.

I have been much struck by the ease with which such cases may be mistaken for abdominal conditions. A few years ago I saw in consultation with Dr. E. S. Scott, of Hampstead, a patient who some years before in America had been the subject of repeated attacks of sickness and vomiting with abdominal pains. He had first an abdominal operation which was followed by a few months of freedom from the attacks; on their recurrence, however, a second operation was done, also followed by temporary relief. What the operation was it was impossible to say, but he had two distinct large abdominal scars. The attacks had recurred when Dr. Scott saw him, and he found on examination that he had Argyll Robertson pupils and absent knee-jerks, and I could only confirm the view he had adopted that the case was one of tabes with gastric crises, and that two unnecessary abdominal operations had been carried out.

It was only a few weeks after this experience that I was asked to see at Moorfields by my colleague, Mr. G. Coats, a man who came there on account of failing vision. His previous history showed that he had had three abdominal operations at a London hospital on account, as he said, of "gastric ulcers." He certainly had three abdominal scars. His condition was one of tabes with optic atrophy, and there was little room for doubt that the three operations which had been carried out with the view of relieving abdominal symptoms were really prompted by the severity of the presumably unrecognised gastric crises from which he suffered.

ACUTE VISUAL DISSEMINATED SCLEROSIS.

There is a considerable class of cases of disease—the nervous nature of which later becomes obvious—in which the early symptoms are either visual or ocular, and are therefore of such a nature as to lead the patients to seek advice of an ophthalmic surgeon, either at a hospital or in private. A very striking case of this character was referred to me at Moorfields some months ago by Mr. W. T. Holmes Spicer. The patient was a girl, aged 21, who came to Moorfields on account of loss of sight. The history was that for about six weeks she had suffered with headache and vomiting and with great difficulty in walking on account of weakness in the legs. She was free from headache and sickness when she came, but her vision was reduced to perception of light. The reflexes were all normal, and no change in the optic discs was to be noticed. I gave my opinion that the case was one of intracranial tumour. I thought it was probably frontal and that the optic nerves were being directly pressed upon, and that this was probably the reason why there was no optic neuritis. I may briefly summarise the sequel, for we were able to watch it, as I had her admitted to Queen-square. The vision gradually improved until it became nearly normal. This was accompanied by a gradual paling of the discs. The walking power improved slightly, but the girl remained spastic with some ataxy, the knee-jerks were increased in activity, ankle clonus was present with plantar response of the extensor type, and it was then evident that the case was one of acute disseminated sclerosis. I have seen two other cases in which sudden loss of vision—naturally enough suspected to be hysterical—was the first sign in what turned out to be cases of disseminated sclerosis. In those two there was at first no associated weakness of the limbs or any change in the reflexes.

GRAVES'S DISEASE.

I am sure that slight cases of Graves's disease are apt to be missed. In some early ones exophthalmos is not complained of and is frequently not noticeable. In some cases it may be unilateral, and unless one is aware that unilateral exophthalmos is not infrequent in this disease the true significance of the signs and symptoms may not be recognised. Goitre also is by no means constant. It is in my experience especially apt to be absent in men with Graves's disease, and I remember one man with the most striking exophthalmos I have ever seen, and another who lost an eye through ulceration, and in neither case was there any goitre to be detected. The cases of Graves's disease in which the true nature of the illness is apt to escape detection are those in which the patients' symptoms are vaguely neurotic, in which goitre and exophthalmos are not noticeable, yet examination reveals a rapid heart, and inquiry elicits a history of wasting, of severe attacks of diarrhœa, and of considerable cardiac and abdominal discomfort. I believe such a combination of signs and symptoms justifies a diagnosis of Graves's disease.

And might I just add a word as to treatment and its effect in this ailment? Nothing to me has been more striking than—I will not say the curability of this disease—but the tendency to improvement. I always give belladonna in good doses, and improvement, often most striking, is the almost invariable rule. Although I personally place considerable reliance upon the drug, I have not implicit faith in it, for I have known patients in whom it failed to effect improvement become quite well without it. And I believe that given fairly good conditions the great majority of cases of this disease tend to improvement, and I have never yet seen a case in which I have thought it necessary to advise operation.

Such are a few of the points which I wished to bring before you, and I trust they may have excited your interest and may lead to discussion.

VENEREAL DISEASE: ITS PRESENT AND FUTURE.[1]

BY DOUGLAS WHITE, M.D. CANTAB.;
AND
C. H. MELVILLE, M.B., C.M. EDIN., D.P.H.,
LIEUTENANT-COLONEL, ROYAL ARMY MEDICAL CORPS.

THE problem of venereal disease, and that of feeble-mindedness, are the two most important medico-social problems of our time, and inasmuch as venereal disease augments the ranks of the feeble-minded, the two questions are closely allied. Of the ravages of venereal disease the public know nothing and consequently care nothing, while those who do know seldom care to break the professional silence, which accords with popular prejudice and apathy. In attempting to deal with this subject, while each of us is, strictly speaking, responsible for his own section, we are, nevertheless, at entire unity as regards the principles and methods by which this problem has to be grappled.

What is venereal disease? What is the present state of affairs? How are we to deal with it? These are the questions to which we invite your attention.

Soft chancre, syphilis, and gonorrhœa—these are the chief forms of disease. The chief importance of soft chancre is its possible confusion with syphilis. Though soft chancre is not a slight or negligible malady, yet both in respect of the gravity of their effects and of the numbers of persons affected, gonorrhœa and syphilis are by far the most important. Their importance is not only individual, but national, since the former affects the procreative powers of both women and men, whilst the latter may and, if neglected, always does result in the introduction into the world of children who are diseased from the very start.

Gonorrhœa is popularly regarded as a mild and not very shameful disease. Medical opinion, however, is doubtful whether, to the individual affected, it is not worse than syphilis. It may be fatal to the victim—more frequently to women than men; its complications and consequences are serious and very common; having no specific remedy of approved efficiency, it is apt, unless treated very early and very thoroughly, to become a chronic disease of indeterminate duration and perpetual inconvenience. Its infectiveness is equally indeterminate. In adults it is only acquired by sexual intercourse. A young man contracting it, and believing himself cured, may then give it to his young wife. Apart from the danger to her person, about 50 per cent. of such infected women are sterile. The majority of all young men get this disease before the age of 30, and

[1] A paper read at the Annual Congress of the Royal Institute of Public Health, held in Dublin, August, 1911.

very many marry while still infectious. In addition to the sterility which they may inflict on their wives they may be themselves sterile by reason of their own disease. The result is disastrous both to wives, husbands, and birth-rate.

Syphilis is only like gonorrhœa in that it is at first, as a rule, locally situate in the genitals of either sex. In the primary condition the local sore alone is infectious. But after a few weeks the blood stream becomes involved and the secondary stage begins. The skin and mucous membranes develop pocks and patches; mouth and throat are invaded, and the infectivity becomes general. Cups which the patient uses, pipes he smokes, cab-whistles, anything which he puts to his lips, may convey the infection to others; for this disease, unlike gonorrhœa, can be inoculated on any part of the body. If untreated he or she may remain a source of infection for about three years. After this the disease becomes latent, ceasing to be infectious to others; but for himself in this tertiary stage no part or organ of his body is free from the chance of invasion or destruction; and at the last he is liable to those diseases which are called para-syphilitic, tabes and general paralysis. Mercury has, indeed, a specific therapeutic effect on the disease, but complete cure by mercury, except under very early and prolonged treatment, is rare. For years after infection it is transmissible to wife and unborn children, who in their turn are liable to the same ills and may even transmit them to the third generation.

The early manifestations of syphilis fill the out-patient departments of general hospitals; the later stages fill the infirmaries and asylums with senseless wrecks of humanity. It is the great-pox. Small-pox we fight tooth and nail, but the great-pox, which is far more disastrous to the nation's life, is left unheeded and unchecked. As for the children of syphilitic parents, it may be said that the first child always dies, either before birth or in the first year (95 per cent.); of all children more than 50 per cent. die before their second year, while most of the remainder are marked with the disease. So we may say gonorrhœa kills the tree before it sprouts, syphilis blights and stunts its growth.

Such is a very brief outline of venereal disease, a rough sketch without colour; every medical man will be able to fill in the colour from his own experience.

The task of estimating the present position, and of suggesting how to deal with it, falls naturally into two divisions, military and civil. As regards the military side, we are in possession of statistics, and the plan of campaign is definite. On the civil side, we have no statistics and no plan of action. First, then, we will take the matter in its more definite and restricted form, returning later to the more general and more difficult side of the question.

Military Section.

The only figures on which we can rely are those furnished by the army, which are to be found in the various volumes of the Army Medical Department Reports from the year 1860 to the present date. The most obvious fact to be gathered from these figures is that the amount of disease now present is about one-eighth of what it was 50 years ago, though in the "eighties" of last century these ailments were distinctly more prevalent than they had been in the years immediately preceding. Since the year 1894 there has been a continuous rapid fall, interrupted only once (1908), when the return of a large number of men from South Africa caused a slight increase in prevalence. The amount of syphilis is now one-seventh of what it was in 1894.

The same phenomena are apparent in the curves showing the incidence of venereal disease in the army of India. The period of absolute maximum prevalence was somewhat later in this case, but the continuous fall commenced much about the same time, and has continued up to the present day.

If we look now at foreign nations, here also our information is mainly confined to military sources. In the French and German armies there has also been a marked decrease in the last 30 or 40 years. Thus in the German army between 1880 and 1888 the admission-rate per 1000 for syphilis alone was 10·2, this being somewhat higher than the average for the "seventies" (This high rate was possibly due to industrial conditions common to both countries.) It has now (1907) fallen to 4·7. The decrease of late years has undoubtedly been due to the tighter screwing up of the military machinery.

The armies of Italy and Austria both show a distinct increase. Thus in Italy, whilst the admissions for syphilis were 8·3 per 1000 in 1884–85, they were 13·3 in 1904–05, and have been in the neighbourhood of that figure for the past 20 years. In the army of Austria there has been a little variation, but the figures have been continuously higher than in the other armies of Central Europe.

The American army, which approaches most closely to ours as regards conditions of service and nationality of its component parts, has shown a steady increase in the number of admissions ever since the commencement of the war with Spain. This is undoubtedly to be attributed to the fact that the annexation of Cuba and the Philippines brought the soldier into contact with races of a lower moral tone than his own countrymen.

If we compare all armies together we note at once a great disparity in the total prevalence of diseases of this class. In the Army Medical Department Report for 1910 a table is given showing the different rates of prevalence in the armies:—

		Per 1000.			Per 1000.
Germany ...	1905–06	19·8	Russia	1906	62·7
France	1906	28·6	United States ...	1907	167·8
Austria	1907	54·2	United Kingdom	1907	63·4

It is interesting to inquire into the causes of the above disparity. The armies of Great Britain and the United States differ from those of the continental nations in the fact that the service is voluntary, while the period over which it extends is comparatively long. Thus the German soldier serves two years with the colours, whereas the British infantry private serves for seven years. The term of enlistment in the American army is longer still and the age at which men enlist considerably higher. Voluntary service necessitates a much higher rate of pay than universal service and the granting of more leisure to the individual soldier. At the same time, the longer period available for instruction permits of some relaxation in the course of training demanded of the soldier. As a consequence, the British private as well as the enlisted man of the United States army has not got his nose held so firmly to the military grindstone as their congeners in the service of the German Emperor or the French Republic. The case was well put by a German officer when discussing the question with an English *confrère*: "When we have finished with our young men in the evening," he said, "they are not in a condition to think of anything but their beds and a good night's rest."

There is one more social condition in which the British soldier differs markedly from those of France and Germany. The German soldier serves his time in or near the town or village in which he lived before enlistment. The British private, once he has left his regimental depôt, probably never again serves in his own part of the country except by accident. The former has, therefore, a certain amount of female society ready to his hand. The latter is left to pick up what society of this nature he wants from that most readily available on the streets of a garrison town.

I cannot help feeling that the blame rests greatly on the shoulders of the civilian population. In England it is by no means an unknown thing for a soldier to be refused refreshment at a public bar because he happens to wear the King's uniform. Such an event in Germany is inconceivable, and there the consequences to any individual guilty of such an outrage would be extremely serious. In this country the insult to the national uniform does not appear to affect even the renewal of the licence. Matters have improved, doubtless, since the South African war, and the extended manœuvres of late years have made the people of the country-side better acquainted with the soldier, the excellence of whose behaviour on these occasions has been repeatedly testified to by local magistrates. The more intimate acquaintance with military affairs which, it may be confidently hoped, will result from the present Territorial scheme should also have a good effect.

The soldier in the ranks is at a very impressionable age; his character is in 99 cases out of 100 what his associations make it, and his behaviour in an equal number that which he thinks people expect of him. When civilians, of social status somewhat superior to the private, learn to look on the wearing of His Majesty's uniform as the honour that it is, and pay the wearer the respect that he deserves for being ready to give his life in defence of their purses, then the soldier will respond by behaving in a manner befitting that respect. The enormous majority do it now, and have always

done it, with very little encouragement from the civil population. With regard to the minority who do not, one may say to the nation at large in the words of Mr. Kipling:—

On your own heads, in your own hands, the sin and the saving lies.

There is yet another distinction in the conditions under which English and American soldiers on the one hand, and those of the Continent on the other, live, and that is concerned with the regulation of prostitution. As is well known, compulsory registration and periodical examination of prostitutes have been until recently nearly universal on the Continent. In these islands it was once tried and relinquished; in America it has been attempted on a few occasions but never persisted in.

It is quite open to advocates of repressive measures to argue that the great preponderance of venereal diseases in the two armies of Great Britain and the United States is due to the absence of such laws in those countries. There is only one point, however, which they must at the outset make good, and that is to prove that the incidence of venereal diseases amongst the civilian population of London bears the same relation to that amongst the civilians of Berlin and Paris as the admissions for the same class of ailments in the British army bear to those in the German and French armies. If repressive measures are efficacious they must protect the civilian as well as the soldier. If they do not protect the former, then a low rate of incidence in the latter must be due to some other causes than regulation. The question as to the incidence of disease in the civil population will be dealt with in the later part of the paper.

The most definite fact of which we are in possession is that the admission rate for venereal disease in our army has fallen greatly in the past 25 years, that for syphilis having decreased by four-fifths. An investigation of the causes of this fall, which has affected the entire force both at home and abroad, may throw some light on the prospects of future reduction, and also perhaps indicate the lines on which we should work with a view to attaining that end.

In the first place, then, the reduction is in no way connected with repressive measures. These were in force under the name of the Contagious Diseases Acts in 14 selected stations, in greater or less severity, from 1864 to 1886, in which last year, in deference largely to popular agitation, they were repealed. During the earlier part of that period their enforcement synchronised with a decided fall in the admissions in the protected stations, whilst those from the unprotected stations remained practically stationary. The initial fall in the protected stations did not, however, continue, and for the ten years prior to repeal in 1886 there was a steady increase in all stations, protected and unprotected.

It is open to advocates of the system to urge that the opening fall was due to the rigid enforcement of the Contagious Diseases Acts, whilst the subsequent rise was the result of a lax enforcement of the regulations, due to their unpopularity with the general public. This does not explain the simultaneous rise in the unprotected stations, though it might be suggested that during this period a general increase in these diseases occurred, which regulation was able to check in the case of the protected stations, but not entirely to prevent. This last argument of course weakens the position of those who hold that repressive measures can absolutely prevent disease. It is difficult on either line of argument to explain the steady fall throughout the army which began almost in the year of repeal, and has continued ever since. In India again the enforcement of regulation did not prevent a steady rise, whilst the discontinuance of this system has not interfered with the subsequent fall.

The evidence, then, points clearly in my mind to the fact that, whatever other effects regulation of prostitution may have, the stopping of venereal disease is not one of them, and whatever the results may be of repeal, it is not incompatible at least with a diminution of admissions from this cause. Continental military medical officers have come pretty generally to the same conclusion, more especially in France, where it is recognised that clandestine prostitution, which avoids regulation, practised by waitresses at low-class restaurants, servant girls, and others, is the predominant cause of disease.

The true explanation of the diminution in the admission-rate of amount of venereal disease in the army lies, I believe, in an improved moral tone amongst the men, accompanied by a decided increase in temperance. This last is, in my opinion, the most important factor, but I wish to emphasise the point that by temperance I do not mean total abstinence or the signing of a pledge. The temperance that needs to be fortified by some adventitious aid such as the wearing of a badge is often the sign of a nature so weak that if it is bolstered up in one direction it is apt to collapse in another. The temperance to which I refer is that which enables a man to take his beer in the quantities that are suitable to him, that enables him not only to know when to stop, but also actually to stop at that point. That there has been a great increase in this true temperance in the army is beyond all doubt, and I repeat that it is to this cause that we must attribute the present improvement.

Other causes have coöperated to a certain extent, and amongst these one must include improved methods of treatment and administration. Every man in the army has a record kept of his ailments on what is termed his medical history sheet, and we are thus enabled to keep track of the men who have at any time suffered from any particular disease. In addition, any man who contracts syphilis has a separate record in the form of a syphilis sheet. On this very full particulars of all symptoms and treatment are entered, and the document accompanies the man wherever he goes, so that any medical officer under whose care he comes can tell precisely the stage at which the disease has arrived and the treatment previously adopted. In addition, a special register is kept (the syphilis record) in which the names of all men under treatment from the disease are entered, so that at any moment any medical officer can ascertain the number of men in the station actually under treatment and their identity. The record is not closed until a man has undergone a two years' course of treatment and been free of symptoms for a year. These periods can be extended by the medical officer if he thinks the course desirable.

Improved methods of treatment, which are at present on trial, may enable us to shorten the length of time under treatment, but so far no modification has been made in this direction. The number of admissions to hospital is undoubtedly affected to a certain extent by the adoption of out-door treatment in cases where the symptoms are slight and not obvious to outer view. This applies, however, only to syphilis, and mainly to the secondary manifestations of the disease. The other forms are unaffected, and there the apparent improvement is an actual fact.

For the future we must look forward to strengthening the soldier's moral character by education, and affording his physical energies free outlet in some form of sport. A great deal has been done in the direction of providing rational evening amusements, more especially in India in the Garrison Soldiers' Homes which now exist in most large stations in that country.

It is sometimes suggested that disciplinary measures should be used to punish men who contract venereal disease, such as depriving them of a portion of their pay while in hospital, in addition to the habitual hospital stoppage. The measure has a plausible appearance at first sight, but, like many other similar administrative measures, it would merely defeat its own object by leading to concealment of disease. With the young man who has contracted disease, every effort should be made to encourage him to seek early treatment. There is nothing so dangerous as delay, and any prospect of punishment may tend to lead to this. With the hardened sinner the case is, perhaps, different, and it might be permissible to deal somewhat severely with the man who repeatedly incapacitates himself from duty by contracting fresh disease. Most culpable of all, of course, is the individual who, whilst under out-patient treatment for syphilis, contracts some other form of venereal disease. On the whole, however, it is better to err on the side of mercy than severity in this matter.

In some services it is the rule to provide men with facilities for personal ablution after connexion, and in the United States small "venereal prophylactic kits" are issued. These consist of small packages containing antiseptic solution and ointment and a little cotton-wool. This system was practised largely in the Philippines with success. The issue was preceded by a lecture in which the dangers associated with irregular intercourse were pointed out, and continence was shown to be not only harmless but positively beneficial. Finally, the method of use of the prophylactic kit was described. The obvious line of argument that such a lecture gives rise to in the soldier's mind must be something of the

following nature: "If intercourse is not a necessity, and if, as my officer says, I shall be a better and healthier man without it, why does he go out of his way to show me how I may indulge in it with impunity?" It is no duty of any authority to assist men to be vicious with impunity; such measures are degrading to the officers who have to advertise them and lowering to the men to whom they are addressed.

Civil Section.

When now one turns from the military aspect to the civil there is a complete change. There are no statistics, and if there were we should be at a loss how to deal with the patients, since they do not, as in the army, come under direct control. Yet we must at least try to make some reasonable estimate of the incidence of venereal disease on the civil population, and to suggest the principles and methods by which to combat it.

Now, can we, from the figures which we do possess, draw any conclusion as to our present position? In the Army the figures stand at a quarter of what they were 25 years ago and in the Navy at about half. But the special conditions of the services as regards age and sex make it clearly impossible to argue from these returns to the civil population. The German army, for instance, shows a very low and still decreasing figure—far lower than ours; yet Dr. Blaschko tells us that the civil figures are high, higher than ours, and still on the increase. The army returns, therefore, do not help us.

Then there are the returns of the Registrar-General. Deaths from venereal disease in these returns show in 25 years a decrease of 33 per cent., as also do the deaths from the same cause in infants under one year. This would be gratifying; but death certificates, while true as far as they go, do not always give the whole truth, and sorrowing relatives are probably becoming more and not less sensitive to the contents of these papers, while the doctor is reasonably anxious not to hurt their feelings unnecessarily. So that we should do well to receive these figures with caution.

But there is another class of return which we may, I think, consider of good value—namely, the numbers of recruits annually rejected from the army for venereal disease. This is, indeed, an army return; but it may be considered a fair index of the state of affairs in the young adult civil population. Taking now these returns since 1863, the first thing which strikes one forcibly is the great and steady decrease in syphilis, from the appalling figure of 16 per 1000 to 1·5. The second thing is the steady persistency of other venereal diseases at the level of about 2 per 1000 for the last 40 years, rising in the last five years to 3·5, and still apparently increasing. By these figures, therefore, we should conclude a decrease of all venereal disease to a quarter of its former bulk, the whole decrease having occurred in syphilis.

Syphilis then, from being a deadly pestilence, has become of manageable dimensions, while the inroads of gonorrhœa are increasing. As Sir J. Hutchinson says, this is not a time for panic; but, in our view, it is a time for vigorous and well-considered action. Even if we suppose that syphilis has decreased all round in this proportion, which is very doubtful, the conditions still are serious enough, as we shall see.

Let us go for a moment to Berlin, Paris, and New York. Berlin is a city of 2·1 million persons. Of these about 670,000 are adult males. On a given date in 1900 142 per 10,000 adult males were under treatment. About 4/5ths of the total were recent cases. Of these recent cases 1/6th were syphilis and 5/6ths were other venereal diseases. Their average treatment is given at about 45 days, a liberal estimate as it appears to me. The female incidence is between one-half and one-third of the male, according to the best authorities. This, when worked out, gives us a figure of 85,000 fresh cases of venereal disease annually in Berlin, or 1/25th of the whole population.

Paris is a city of 2¾ millions. There it would appear that about 17,000 persons are annually infected with syphilis, and if the same proportion to other venereal diseases obtains there as in Berlin, we get an annual total of over 100,000 for Parisian venereal disease, or 1/27th of the total population.

New York is a city of 4½ million inhabitants. Dr. Morrow holds that there are "over 200,000 infected persons walking the streets of New York," and Bierhof believes this an underestimate. If we consider this expression to represent the number annually infected, the proportion of the population attacked is about the same as in Berlin or Paris. Here also about 1/6th of the numbers are due to syphilis.

In all these cities about 1/12th of the adult male population are infected annually, and about 1/30th of the adult females. Roughly 1/25th of the whole inhabitants. The significance of such figures may be appreciated when Dr. Blaschko gives as his opinion that in Berlin every man who reaches the age of 30 has (on an average) had gonorrhœa twice, and every fourth or fifth man has had syphilis.

How can we compare London with Berlin? Here again, the recruiting figures come to our assistance. British recruits show—in regard to venereal diseases—a figure at present of 5 per 1000, while those of Germany show about 7½ per 1000. (These are in each case the latest available figures.) Of course, the comparison must show in our favour, because of the far-reaching difference between voluntary and compulsory enlistment; but we shall take these figures at their face-value, since we wish our estimate to be conservative. Let us assume, then, that in Germany the proportion of venereal disease is half again as great as in Britain. London is 3½ times the size of Berlin. Allowing the full deduction of one-third, we reach the figure of approximately 200,000 fresh cases of venereal disease annually in London.

A peculiar interest attaches to the fact that the proportion of disease, and also the proportional number of prostitutes, increase with the size of the town. In German towns other than Berlin of over 100,000 people, the proportion of disease is only 70 per cent. of that of Berlin; in towns of 30,000 and over, 40 per cent. of the Berlin proportion, and so on. Again, in New York there is said to be 1 prostitute to every 57 of the population, while for the smaller towns in the States, of say 30,000, the proportion falls to 1 in 400. It is a question of demand and supply; the demand by a given number of men is greater in the large towns than in the small. Thus there is a close correlation between the number of such women and the amount of disease, the proportion of each rising with the size of the town.

The point of these remarks is this. The large towns of Great Britain, other than London, of over 60,000 inhabitants contain between them about 15 millions of people, or about twice the population of London. Allowing them half the London incidence we shall get another 200,000 per annum: 400,000 cases thus account for 22½ millions, or half the whole population of the United Kingdom. The smaller towns and country, the other half, may be expected to contribute about 100,000. Thus, we should reach a total annual toll to venereal disease in the United Kingdom of half a million.

These are not statistics; they are only reasoned computations, and, as such, are open to reasoned criticism. Rough as they are, they will give you some idea of the calamitous quantity of these diseases, of which I have already described the disastrous quality.

(To be continued.)

TREATMENT OF GRAVES'S DISEASE WITH THE MILK OF THYROIDLESS GOATS.

BY WALTER EDMUNDS, M.A., M.C. CANTAB., F.R.C.S. ENG.,

CONSULTING SURGEON TO THE PRINCE OF WALES GENERAL HOSPITAL, TOTTENHAM.

IN two previous communications[1] the results following this treatment have been recorded; it is now proposed to add further cases and to draw some general conclusions. As to the already recorded cases, the second is now well. The third is extremely important. It was found by careful observation that the dried blood from a thyroidless goat caused diarrhœa, when it was of course stopped; after that no specific treatment was given. The patient became gradually worse; much œdema of the legs came on, and in September, 1911, she died from cardiac failure; in all probability the thyroidless milk treatment was of no benefit in this case. In the fifth case at the time of the last report (December, 1908) the supply of thyroidless milk had stopped, and a few days after this, and apparently in consequence of it, the patient was much worse, more tremulous, weaker, and liable to attacks of pain in the region of the heart, with shortness of breath, attacks which the patient had not suffered from since she first came under treatment nine months previously.

[1] THE LANCET, Jan. 25th, 1908, p. 227; and April 10th, 1909, p. 1040.

She was therefore admitted to hospital, and was there treated with thyroidectin, grains 5, three times a day. She improved under this treatment and left. During the spring and summer of 1909 the patient took the goats' milk, and as the supply was limited she also had X rays applied to the goitre. In the autumn thyroidectin was also given. The patient was now readmitted to hospital. She was much better than when in hospital before; the goitre was much smaller, presumably in consequence of the X rays, and the tumour could be distinguished into a hard central oval mass and two soft, lateral lobes. She remained in hospital a month. After that the X ray treatment was continued for four months, sometimes once, sometimes twice, a week. Notwithstanding the insertion of thicknesses of towel between the lamp and skin some redness was caused. Latterly the patient had to leave the neighbourhood. She writes that the goitre has increased in size.

CASE 10.—The patient was seen in October, 1909. She was better, but the eyes were still prominent; the goitre was firmer.

CASE 11.—The patient was presented with a thyroidless goat, and during the summers of 1910 and 1911 took its milk. She is much better and can ride a bicycle.

To the foregoing the following cases may be added:—

CASE 16.—The patient, a male, aged about 35, under the care of a medical friend, came under treatment in 1908. During the winter 1908–09 he was treated with rodagen and thyroidectin, but no improvement occurred; on the contrary, the patient became somewhat worse. It was therefore decided to try a course of rest in bed. Up to this time the patient had been going daily to business, but now for five weeks he rested in bed, and at the same time took the milk from a thyroidless goat. He improved under this treatment, but the pulse still continued fast. He then went to the seaside and discontinued the milk. Here he improved. Now (July, 1911) the patient is much better and attending regularly to business. He has much faith in rodagen, which he therefore still continues to take.

CASE 17.—The patient was a young single woman, under the care of a medical friend. Symptoms commenced obscurely about six years ago. In the spring of 1909 the patient was seriously ill, the main symptoms being a large goitre and attacks of dyspnœa. The patient went to the seaside, and was treated with the milk from a thyroidless goat for 20 weeks. She improved very much. Later the milk treatment was resumed. When last heard of the patient was so much better that she was about to be married.

CASE 18.—The patient was a young woman, suffering from severe Graves's disease; a sister had previously died from the same complaint. For six months during the summer of 1910 the patient took the milk from a thyroidless goat, but there was no benefit apparent, and in the autumn she died. This was a very severe case, and one in which a bad prognosis had been given early.

CASE 19.—The patient was a single young woman, suffering from Graves's disease of moderate severity. Enlargement of the thyroid first noticed five years ago; the Graves's disease was at its worst about 18 months ago. The patient went into the country, where she had the milk from three thyroidless goats, and was much better at the end of the summer.

Remarks.—The effect (if any) of the treatment of Graves's disease with the milk from thyroidless goats or preparations made from it must depend in a considerable degree on the dosage. Clearly a sufficient dose must be given. One of the preparations is said to be made by mixing the dried milk with an equal quantity of sugar of milk, which is added as a preservative; one ounce of dried milk would correspond with about four ounces of the whole milk. If, then, one-drachm doses of the mixed powder were given, each dose would correspond to two drachms of fresh milk; and if the doses were ordered three times a day they would correspond to six drachms, or possibly one ounce, of the milk a day. But when the fresh milk is given it is usual for the patient to take the whole yield of one goat, which may be a pint or a quart a day; sometimes a litre (35 ounces) is prescribed. In one of the cases above recorded the patient was taking at one period about two quarts of the milk a day; if this is anything like the right dose (and it certainly did no harm) three drachms a day of the powder would be much too small. Further, to give the powder on the scale the fresh milk is given would cost about 33*s.* a day.

It is thought that the symptoms of Graves's disease are due to excess of thyroid secretion in the circulation. Some experiments were made on this view. Rats were given doses of thyroideum siccum half a grain twice or thrice a day, and were fed, some on the milk of normal goats and some on that of thyroidless goats. All the rats died from thyroid poisoning, but the rats fed on the normal milk lived longer than those fed on the thyroidless milk.[2] This difference cannot be accounted for by any difference in the amount of calcium in the milk, because Mr. Cecil Revis found in an analysis he kindly made for me that the amount of calcium was practically the same in the two.

The part that calcium plays in the results of complete removal of both thyroid and parathyroids is remarkable. Dogs and cats fed in the ordinary way almost always die within a week of the operation with symptoms of tetany; if, however, they are fed on milk only, and given lactate of calcium in addition, they will in many cases recover. I have now two dogs and one cat which have been living in good health without either thyroid or parathyroid for months, but they are being fed almost exclusively on milk. On this account calcium lactate has been recommended in the treatment of Graves's disease. There is no objection to this, but it may be pointed out that these patients are often taking a considerable amount of milk, and that ten grains of lactate of calcium only contain the same amount of calcium as there is in two ounces of cow's milk.

The tremors of Graves's disease are certainly suggestive of the tremors which occur after total excision of thyroid and parathyroids, and as calcium is of immense importance in the treatment of these it seems advisable to give it in Graves's disease. The best way to do so is by giving milk, either cow's milk or goat's milk, but there is no strong evidence that the milk of a thyroidless goat is better than that of a normal goat. Moreover, the theory on which the "anti-thyroid" treatment is based is not above criticism; removal of the thyroid gland in goats must tend to produce, indeed sometimes it does actually produce, myxœdema. This tendency should cause an antimyxœdema body to be formed; this would be a pro-thyroid body and tend to make Graves's disease worse. Again, Graves's disease is not unfrequently followed by myxœdema, and in some cases the symptoms of the two diseases coexist. It seems, therefore, probable that in long-standing cases we may have to treat not hyperthyroidism itself, but its permanent secondary effects combined very possibly with a certain amount of hypothyroidism.

Dr. John Rogers, of New York, has prepared a specific serum for the treatment of thyroidism, to which condition he attributes the symptoms of Graves's disease, and he gives a report of 42 cases in which the serum was used.[3] A satisfactory case of the treatment with the milk of a thyroidless goat is recorded by Sir Thomas Myles.[4] Similar results have been obtained by Dr. J. R. Gilmour, of Scalebor Park,[5] and another satisfactory case is reported from Scotland.[6]

Devonshire-place, W.

ENURESIS AND THYROID EXTRACT.[7]

BY A. C. D. FIRTH, M.B., B.C. CANTAB.,
MEDICAL REGISTRAR, WEST LONDON HOSPITAL.

IN 1909 Dr. Leonard Williams published some striking cases in which thyroid extract had proved beneficial in cases of nocturnal enuresis. In his paper[8] he states, "We have seen in all 25 cases; of these only one has failed to respond to the thyroid treatment." Stimulated by these results, I commenced to treat some cases with this preparation. In all 28 cases were treated at the Victoria Hospital for Children, unselected and consecutive, and a record kept of pulse, temperature, weight, and number of nights during which enuresis occurred. The children attended hospital once weekly, and, as far as possible, no change was made in their mode of living while the thyroid extract was being administered. Adenoids were not removed, although this has been done in several cases since, and no anthelmintic was ordered

in cases harbouring threadworms. When the mothers had been in the habit of "lifting" the children on retiring themselves, they were instructed to continue the practice, but where it was not done, this method of treatment was not recommended. Of the 28 cases, 16 showed a marked improvement or were cured, and 12 did not improve at all.

For purposes of comparison the cases have been divided into two groups—A, those with improvement; B, those without improvement. In both groups the figures are too small to allow the slight variations in age (at which treatment was commenced) or sex to be of value. The remarkable preponderance of females over males, 19 to 9, seems to be usual, as of the last 89 cases of enuresis attending hospital, 61 were females.

The most striking feature of Group A was the number of backward children it contained; 12 out of 16, compared with 2 out of 12 in Group B. The mental condition was necessarily founded on the report of the mother or school teacher, and was ascertained in all cases before treatment was commenced.

The cases which appear to react to this form of treatment better than all others are those in which the enuresis has persisted since birth, and in which the patients are also backward. There were 5 of these cases, all of which showed marked improvement. Seven cases with enuresis from birth were stated to be quite satisfactory as to the mental condition, and only one of these improved. Of the 16 cases in which the enuresis started during childhood, 6 out of the 10 improved were backward compared with 2 out of 6 not improved. The duration of the acquired enuresis was of no importance in prognosis.

In 7 cases in Group A hypertrophy of tonsils and adenoids was present, and 4 had undergone operation for this condition. In Group B 4 children were similarly affected, and one child had had them removed. In no case could any connexion be traced between operation and enuresis. In no case could the enuresis be ascribed to the genitalia, whilst threadworms had been noticed in 3 cases of those improving and in two cases amongst those who received no benefit by treatment. In 3 cases the enuresis could be traced to a definite exciting cause, an operation for hernia, scarlet fever, and enteric fever respectively. The first of the cases (No. 2) was cured, but the other two (Nos. 13 and 14) did not respond really well to the treatment.

An attempt was made to obtain data for controlling the effects of the thyroid extract from observations on the pulse, temperature, and weight. The pulse-rate did not give any definite evidence of overdose until diarrhœa commenced, and showed wide variations in uncomplicated cases. Had the children been under observation in hospital where the pulse could have been recorded twice daily, thyroidism would probably have been detected by the increased pulse-rate before the onset of diarrhœa made it obvious, but a weekly attendance and the likelihood that the accompanying excitement will disturb the pulse-rate seem to render the pulse an untrustworthy guide, and to explain the differences noticed for which no definite cause could be otherwise assigned.

The temperatures were taken in the rectum and varied between 98° and 100° F. before treatment commenced; all cases except five showed an average rise of about 1° while under treatment, but there was no distinctive feature about the behaviour of the temperature in either group.

The initial weights showed more variation—according to the table given by Holt[9] the percentage of children below normal was equal in both groups, but of the cases showing a weight of 6 lb. or more below the average Group A contained 50 per cent., compared with 30 per cent. in Group B. The children, with one exception, gained weight while taking thyroid extract, and no reason could be found to account for the exception.

The initial dose was ¼ or ½ grain daily and the rate of increase varied much as the work was experimental; often the dose was increased every 14 days. In some cases which showed improvement, but in which the condition had become stationary, the same dose was continued for a month or more. The accompanying table gives the rate of improvement and the doses administered each week to the children in Group A. Nos. 13, 14, and 16 can only just be called improved; six cases—Nos. 1, 2, 3, 5, 9, and 10—also suffered from diurnal enuresis, and this condition was cured in every case.

[9] Diseases of Infancy and Childhood fourth edition, p. 20

As it is most important to ascertain if the improvement following the administration of thyroid extract is permanent a note was sent to the parents of all the cases in this group inquiring into the condition of the child. Replies were received in ten cases, and together with a few brief explanatory remarks are given below. When a period of time is given the interval between the cessation of treatment and the receipt of the reply is indicated.

Remarks upon the cases.—1. Three months. No recurrence.—2. Six weeks. No recurrence; dose gradually reduced after twelfth week.—4. Eight months. "Never more than twice weekly and often less."—5. Quite cured: enuresis gradually ceased.—6. After the twelfth week the child attended for 14 days, taking the same dose with no variation in the enuresis. Chorea then developed and the treatment with thyroid extract was discontinued.—8. Six months. Enuresis only occasionally, about once a month.—9. Treatment was stopped for diarrhœa. The patient's mother reported to me at the end of the first and second months following cessation of treatment that enuresis had occurred six times during the first month and four times during the second.—10. Five months. The patient only wets the bed when her mother "forgets to lift her."—11. Seven months. The mother expressed her regret that she had ceased to attend, and reported that the boy still wetted the bed on an average twice weekly.—12. Six months. Has only wetted the bed about half a dozen times in all.—13. Although included in the table this patient was eventually cured by atropine. During the last three weeks the child took 4½ grains of thyroid daily with the result shown. Immediate improvement took place when liq. atropinæ was given, and after five weeks the enuresis ceased. This child was not at all backward, and although the case is included in the table to show that some benefit accrued from thyroid extract the real improvement is attributable to the atropine.—14. This patient continued to attend at irregular intervals for nearly two months after this, and was at one time taking 2 grains in 24 hours. The enuresis still occurred on two or three nights per week, and when I saw the child with scarlet fever a year after treatment had first commenced the condition was unaltered.—15. Attended another three months at intervals of 14 days, taking the same dose with the same result. The patient then discharged herself, but three months' later was reported as only wetting the bed one night a week or less.

A table of the unsuccessful cases is not given, as the treatment followed exactly the same lines and lasted on an average five weeks, except 3 cases which extended over 12 weeks or longer. No improvement of any sort could be detected. Diarrhœa caused the treatment to be abandoned in 4 cases, and the occurrence of this complication, five times in 28 cases, was the only difficulty encountered; it soon ceased when thyroid extract was not given, but it indicates the necessity of using small doses on commencing treatment and careful observation afterwards. Three of the patients, aged 5, 8, and 11 years respectively, were taking 1 grain, and one, aged 9 years, 1½ grains in 24 hours. The fifth case, a boy, aged 4½ years, appeared to be extremely susceptible, as he developed diarrhœa on a half-grain dose daily. The weight of all these children was within a pound or two of the normal, and none of them had been classed as backward. Case 13 in the table was also probably an example of overdose. When in the ninth week improvement commenced, the dose was rapidly increased, and was followed by a relapse till finally the last stage was as bad as the first. Dr. Leonard Williams quotes a somewhat similar case.

In the unsuccessful cases the treatment was abandoned when a dose of 2 grains in 24 hours failed to produce even slight improvement, as it seemed that any case which would improve showed signs of so doing before this amount was reached.

It cannot be asserted that the results obtained were nearly as satisfactory as previous accounts have led us to expect, but when we consider that two cases were cured, that nearly 60 per cent. of the cases showed marked improvement, that of these all except one had suffered from enuresis every night in the week and many for a considerable period, it is evident that thyroid extract has taken a definite place in the treatment of enuresis, and in certain cases may be exhibited with more confidence than any other drug with the exception of belladonna.

Table showing Results in 16 Cases of Enuresis Treated by Thyroid Extract.

Case.	Years of age.	Duration of enuresis.	Number of nights per week in which enuresis occurred before treatment.	After treatment commenced—	Week of treatment. 1st.	2nd.	3rd.	4th.	5th.	6th.	7th.	8th.	9th.	10th.	11th.	12th.	13th.

16	12	3 years.	7	Enuresis	3	3	4	3	2	Ceased attending. No reply to card.							
				Dose	½	1	1	1½	1½								

* Developed chorea. † See No. 15 under "Remarks upon the cases."

The dose, it must be noted, was much smaller than that given in Dr. Leonard Williams's series of cases, but five cases of diarrhœa in a total of 28 could hardly be coincidence. That the diarrhœa ceased when the thyroid was withheld and that only one case, that of a boy 11 years of age, occurred during the hot weather (1910) reasonably prove the thyroid was the most probable cause.

When the child is backward, slow at school, or displays other signs of mental lethargy, and especially if the weight be markedly below the average, the use of this preparation holds out a very fair prospect of success. Definite and permanent improvement appears to occur, even if the cure is not absolute, for not one of the replies received indicates serious relapse.

The dosage employed was doubtless rather small, but the onset of diarrhœa in two of the early cases rendered me chary of administering the drug in large doses to out-patients, and its occurrence in three more cases confirmed me in this, but possibly with a more rapid—i.e., weekly—increase of dose more speedy results would have been obtained.

As indicated above, both pulse-rate and temperature are untrustworthy, when only taken once weekly, in providing danger-signals of thyroidism, again an argument in favour of caution; but where the patient is under constant observation, as in hospital, the dose might be rapidly increased with safety, especially in the case of the undersized, backward child.

Eight children in the second group were treated with atropine, and of these 5 showed marked improvement. I have had little experience of the effect of thyroid extract in cases in which belladonna has failed, 2 only, both encountered after drawing up this series of cases, and both up to the average standard mentally and physically.

In the days before thyroid extract had been suggested as a cure for nocturnal enuresis, I saw some cases in which the improvement caused by atropine in backward children was as marked as the cases of this series treated by thyroid extract, and it seems probable that if an equal number of unselected cases were treated with atropine alone the results would be as good, if not better, and that the greater percentage of unsuccessful cases would occur amongst the type of child commonly called "backward," the type in which thyroid extract is most successful.

THE USE OF ROSENBACH TUBERCULIN IN SURGICAL TUBERCULOSIS.

BY GEH. MED. RAT PROF. DR. FRIEDRICH J. ROSENBACH.

(*In Charge of the General Surgical Clinic of the University in Göttingen.*)

THE treatment of surgical tuberculosis is at present one of the most unsatisfactory tasks of the medical man. Advanced, serious, and extensive disorders, as well as quite recent but easily accessible foci, frequently repay, it is true, radical operations. On the other hand, many local manifestations of tuberculosis—e.g., spinal tuberculosis—cannot be submitted to radical operations at all, others only by the sacrifice of functions or of appearance or by mutilation. In recent cases when the symptoms are slight it is difficult for a medical man to decide on such operations. He is uncertain whether the sacrifice will bring about even local cure, let alone complete freedom from tuberculosis. He is therefore bound to have recourse to less radical measures, such as fixation, the congestion method, and general treatment, whilst awaiting any further development which may prove favourable. Naturally this is not the ideal treatment, such as might be sought in an effective chemotherapy. Here some slight progress has been made by the injection of iodoform into tuberculous joints, but for general application in tuberculosis this remedy has not proved any more valuable than the countless other attempted remedies.

During a general clinical and surgical activity of 36 years I have tried chemical agents of every sort against local tuberculosis, without any real success. In the face of the

unsuccessful use of Koch's Alt-tuberculin I had no leaning for a long time towards immune therapy—that is, the use of tuberculin. At last, I did indeed come to treatment by tuberculin, but using a new tuberculin. A study of the biochemical reciprocal effects of bacteria and plants led me to submit a culture of tubercle bacilli to the action of a trichophytonmyces. From this resulted the preparation of a new tuberculin, in which the poisonous constituents are destroyed and the immunising constituents preserved.[1] The firm of Kalle and Co., A.G., Biebrich-on-the-Rhine, has undertaken the manufacture of this new tuberculin and under my control has delivered large quantities to hospitals and clinics for experimental purposes, the quality of which has been uniformly unexceptionable.

This tuberculin is used in two ways: the first is by means of subcutaneous introduction into the circulation for the treatment of inaccessible local tuberculosis. It is then, like other tuberculins, retained in the foci by elective combination. It here produces inflammatory exudation with accumulations of leucocytes, absorption of tuberculous tissue, and thus a pronounced curative process. The second method of administration is by means of direct injection into the diseased foci—e.g., joints, tendon sheaths, lupus, &c. In this case the tuberculin produces the same process, but much more intensely. The inflammatory exudation and the leucocytic infiltration is as intense here as in acute cellulitis. The soft parts become very red, are hot to the touch, hard, painful, and there is extensive swelling. Any hollow spaces existing—e.g., joints—are extensively filled with fluid. At the same time general symptoms are observed, such as indisposition and increase of temperature. All these symptoms disappear at once without doing any harm and leave behind a striking improvement of the tuberculous affection. Where the tissue has not yet suffered any vital damage from tuberculosis—that is, where there is no ulceration, granulation, caseation, &c.—it is often possible that a few injections completely cure joints and tendon sheaths, &c., in particular where tuberculous infection is recent.

On the other hand, parts where ulceration, granulation, caseation, and necrosis are already present become inflamed, so that suppuration accompanied by indisposition and fever ensue, and closed parts—e.g., joints—open and discharge this pus. Even then, if the treatment is continued, a cure with contraction is possible by the gradual expulsion of substances which are not capable of absorption, but, as a rule, the cure must be completed by operation, scraping, thermocauterisation, removal of affected bones, articular resection, &c. Even in lupus it is necessary, after the affection has been diminished and softened by the injections, to remove the affected parts by operation.

I have treated a number of cases of surgical tuberculosis with Rosenbach's tuberculin, and last year I reported three of them,[2] but at that time under reserve of further observations, so as to convince myself that the results were permanent and the treatment satisfactory. At present my earliest cases have been under observation from two to three and a half years, and subsequent tests with this specific are being carried out in many clinics and medical institutions.[3] For this reason I feel it a duty to publish the record of my experiences. In order to facilitate a right judgment of its merits, and further to assist those medical men who might wish to apply this treatment in forming an idea of the method of administration, where and how it should be applied, its value and what is not to be expected of it, I will first make a few general remarks.

The treatment of tuberculous disorders by tuberculin belongs in no sense to chemotherapy, that is to say, it in no way relies on a poisoning of the tubercle bacilli by chemical substances, as, for example, the treatment of syphilis depends on poisoning of the spirochætæ by mercury, iodide of potassium, or salvarsan. It would be of the highest importance if an analogous remedy could be found for tuberculosis. It has indeed been sought by medical men from the earliest times, but without success. While for a long time a very effective specific treatment of syphilis by various chemical substances has been possible, no chemical specific has ever been found which could stand comparison with those specifics used in the treatment of syphilis, so that up to to-day there seems no hope of any specific chemotherapy of tuberculosis, and until such a specific is found Koch's great discovery of the antigen treatment is of supreme importance.

This treatment by means of tuberculin is therefore a part of the therapy of immunity, but among the methods of this therapy it stands in a peculiar position. The treatment of acute infectious diseases depends largely on the method of so-called passive immunisation by sera of immunised animals, because this is the only way in which sufficient quantities of antitoxin substances can be quickly introduced into the affected body. On the other hand, as a prophylactic agent the more effective and more permanent active immunisation process has been exploited; its greatest achievement is Jenner's vaccination against small-pox. In acute infectious diseases, if infection has already taken place, active immunisation has only been successful in rabies, where it has time to develop on account of the long period of incubation. As a matter of fact, this also, strictly speaking, is a question of prophylaxis, for if the rabies has already declared itself or is imminent, no cure can be obtained by this method. In the treatment of tuberculosis, however, the demand is that an affection of long standing shall be successfully treated by active immunisation, the tuberculin cure. It is assumed that owing to the chronic condition of the disease and its localisation the organism has still sufficient power of biochemical function to react to the stimulus of antigen and to form antitoxin substances. The answer to the question whether this assumption has any real foundation can be only decided by clinical experiment. To a large extent this experiment has already taken place in the application of Koch's Alt-tuberculin, and in spite of early failure results have been achieved in the second tuberculin period so far positive that in certain circumstances the disease can be satisfactorily influenced. Even in cases of pulmonary tuberculosis reported in my paper[4] a quite favourable effect of Rosenbach's tuberculin cannot be denied. The cases of surgical tuberculosis to be reported are, however, still better adapted to demonstrate the influence of this tuberculin. It is not claimed even in these cases that the treatment with Rosenbach's tuberculin goes beyond the therapeutics of immunity, and in order to appreciate the results it is necessary clearly to see how far and in what cases the therapy of immunity is affected and what are its limitations.

Particular weight must be laid on the following three factors of the action of the immunised body. The first refers to the effect on the disease-producing microbes in the immunised organism. It has been proved by experiment that these microbes, if introduced into animals immunised against the disease, can be supported in deadly doses, whilst the microbes are themselves considerably affected and to a great extent destroyed, but not completely killed and extirpated. This fact has been experimentally demonstrated in animals for the bacilli of cholera, typhoid, pyocyaneus, and anthrax among others. As these bacilli cannot live in the animal as long as the immunity lasts, recurrence of the disease is not to be apprehended. This, however, is not true of all microbes, and in particular of the tubercle bacillus, which is known to have the power of existing in living tissue for years or a whole lifetime.

The second factor which we have to consider is the fact that the immunity only lasts for a definite time. This period is certainly in the case of Jenner's inoculation against small-pox a very long one, but in other diseases it is relatively short, so that if, on the one hand, the microbes remain alive in the body, and on the other hand the immunity disappears too soon, the danger at once arises of recurrence of tuberculosis. The case, however, is not so unsatisfactory as it might appear. The extraordinary vital tenacity of the tubercle bacillus is bound up with special conditions, such as, for example, are found in cases of facial lupus, while in other places complete disappearance is very frequent. I would draw attention to frequent chance post-mortem results in cases of cured pulmonary tuberculosis and to the frequent cures of articular, spinal, and peritoneal tuberculosis which follow without treatment or only by fixation, opening, congestion, &c. For this reason I believe that the cures to be reported, brought about by the activity of Rosenbach's tuberculin, are now, after the lapse of one to three years, to

[1] Deutsche Medicinische Wochenschrift, No. 33, 1910.
[2] Loc. cit.

[4] Loc. cit.

be regarded as permanent. A permanent cure of lupus generally necessitates a longer treatment. I shall return to this subject.

The third factor—a very important one—of treatment by production of immunity is the fact that the healing power of this treatment is stronger and more certain the more recent and less developed the stage of the affection and the weaker in proportion to its long standing and development. Treatment with Rosenbach's tuberculin is contra-indicated in the last stages of phthisis, in serious affections before this state, and in cachectic cases with severe surgical tuberculosis. Nevertheless, from time to time hopeless cases have shown a transitory improvement, and very serious cases have been permanently relieved and even cured. In recent cases surprising results may be observed such as have hitherto never been known. Besides the reported methods of useing Rosenbach's tuberculin the medical man in charge of the case must note that this tuberculin, when introduced into the tract of fistulæ and open cavities, only produces superficial inflammation, and is expelled with the secretion without doing good.

To produce a cure the injection must be made into the walls of open fistulæ and cavities, after surgical treatment of the latter.

Diagnosis of tuberculosis with Rosenbach's tuberculin.—If after subcutaneous injection of 0·2 c.c. in the upper arm, for instance, there is no cutaneous reaction, this injection is to be repeated on the following day with 0·3 c.c., and perhaps even with 0·5 c.c. on the third day. Cutaneous reaction denotes a positive result. From time to time symptoms of irritation appear at the site of injection in patients unaffected with tuberculosis. These symptoms, however, are different from the typical cutaneous reaction in cases of tuberculosis.

Report of Clinical Observations, referring in all to 47 Cases.

1. *Tuberculosis of the large joints.*—Treatment: Local treatment was particularly successful. Injection into the cavities of the joints produced sure and rapid effect. When the case particularly indicated such treatment (in cases of tuberculous affection together with the articular affection), the subcutaneous treatment was adopted with the local or by itself. It was also often adopted at the beginning of the treatment of a joint in order to alleviate the first reaction in the joint. Dose: The initial dose, except in peculiarly sensitive cases, was almost always 0·2 c.c. Rosenbach's tuberculin. This was so even in the case of a child of 1 year 9 months. On repetition the doses were increased by 0·1 c.c. If the reaction was strong the doses were not increased so often. The time for the repetition of the injection depended on the reaction, the condition of the patient, and the quantity of the dose. Small doses with slight reaction were often repeated on the following day because they were too small. Other doses producing a perceptible reaction were only repeated on the third to the seventh day, and others producing intense reaction were only repeated after eight to ten days. In the hip-joint the last big doses were only repeated after two weeks. Often the patient for other reasons wished the doses repeated at long intervals. This is, of course, inexpedient. As, however, the effect of the injections persists for months treatment may be of value with long intervals. When the reactions left off or became weaker in spite of increased doses the treatment was for the time regarded as at an end.

Of 4 cases of tuberculosis of the elbow 2 were cured after a few injections with very satisfactory functional results. The permanency of the cure was demonstrated 1 year 9 months and 1 year 5 months after the beginning of the treatment. In 2 cases abscesses were formed. These were cured by resection. I must here lay stress on the fact that abscesses following on injections of Rosenbach's tuberculin must not be regarded as failure but as success, because in this way an operation is at once indicated and long and fruitless conservative treatment is frequently avoided.

Of 5 cases of tuberculosis of the knee-joint 4 were cured, and in 3 cases with very good movement, in 1 case less so. The permanence of the cure was demonstrated in 2 cases 1 year 4½ months, in 1 case 1 year six months, and in the fourth case 1 year 1 month after the beginning of the treatment. The fifth case (subchondral osteitis) was treated by resection and cured. Of 3 cases of tuberculosis of the hip-joint 2 were cured, in 1 with good movement, in the other limited. The permanence of the cure was demonstrated 1 year 9 months and 10 months 20 days after the beginning of the treatment. One case was successfully treated by resection. Of 3 cases of tuberculosis in the foot 1 was cured by the injections, and the permanence of the cure was demonstrated ten months after the beginning of the treatment. Two cases developed abscesses and were treated by resection.

Of 16 cases of articular tuberculosis 9 were cured by treatment with Rosenbach's tuberculin; in 7 cases purulent inflammation resulted and they were cured by resection.

2. *Tuberculosis of the spine.*—Spinal tuberculosis was treated by subcutaneous injections. There is no certain criterion for the cure of spinal tuberculosis. Nevertheless, three of the seven cases treated were certainly cured, the permanence of this cure being demonstrated in the first case 1 year 8 months, in the second 3 years 3 months, and in the third 3 years 7 months after the beginning of the treatment. In the latter case a bilateral purulent burrowing abscess was completely cured. It is very probable that three of the other cases were cured, and in any case improved. In one case of tuberculosis from infancy tuberculous meningitis supervened four months after the end of the treatment and the patient died.

3. *Tuberculosis of the tendon sheaths.*—Tuberculous bursæ were treated like the joints with local injections into the cavities and in the vicinity of the abscesses when formed. Three cases were cured with complete power of function, once without and twice with abscess and suppuration. The permanence of the cure was demonstrated 1 year 5 months and 1 year 7 months after the beginning of the treatment.

4. *Glandular tuberculosis.*—In 2 cases the tuberculin was introduced by subcutaneous injections. In each case the affection was diminished, once with induration and calcification, the other case with suppuration and abscess, once extirpation, once scraping. The permanence of the cure was established 1 year 1½ months and 1 year 3 months after the beginning of the treatment. Local injection first into a gland and after the extirpation of the gland into the induration remaining caused abscess, suppuration, and cure. The permanence of the cure was established 6 months and 1 year 3 months after beginning of the treatment.

5. *Recurrence of tuberculosis, fistula, and fistulous abscess in the soft parts.*—In two cases there was a recurrence of affection after operations on the bone. The first case was fistulous, the second closed. They were cured by injections into the tissue, the bone lying free at the bottom being in one case removed. The three other cases concerned fistulous subcutaneous abscesses. They were cured by injections into the walls, in 2 cases with scraping. The permanence of the cure was established 9½ months, 1 year 6½ months after the beginning of the treatment.

6. *Lupus.*—Treatment: Local injection into the cutis under the part affected. Dose increased and intervals between injections as in the treatment of the joints. During the treatment the injections should be made uniformly in all parts affected by lupus. The local reaction varies from moderate to severe, with secretion, similar to acute cellulitis, which disappears very quickly. After several operations the lupus is diminished, improved, and softened. Beside local reaction there are general symptoms of fever, indisposition, and loss of appetite. In course of time the reaction decreases in spite of increased doses. It is at this time that operation must be made. When the extent of the affection is reduced and the position allows it the remaining lupus areas should be cut out and either sutured or grafted or else scraped and cauterised. In cases of recurrence the injections and operation on the same principle are repeated and the last remnant cut out. Recently I have used another method. After the cure produced sooner or later I have made trial injections, my intention being in the case of reaction to proceed with renewed injections as a precaution against recurrence. Of 11 cases of lupus, in 10 subjects 4 were cured by a single injection treatment followed by operation. The permanence of the cure was established 7 months, 11 months, 1 year 9 months, and 2 years afterwards. Three patients after being twice treated by injection were cured by subsequent operation. In these cases the cure was established as permanent after 1½, 4, and 9 months. Three serious cases were cured after being treated several

times by injection and operation. In these cases the treatment was long (1 year 2 months to 1 year 6 months); one patient is still under treatment. When the patients last presented themselves the cure had lasted 3 months, and in two cases 3½ months.

7. *Peritoneal tuberculosis.*—A boy, aged 9½ years, had been suffering for 2½ months from peritoneal tuberculosis, and was in a very bad state. He underwent a treatment lasting two months with 34 injections (23·2 c.c. Rosenbach's tuberculin). The permanence of the cure was established 11 months after the beginning of the treatment. Increase of weight in that time 6·5 kilogrammes.

8. *Intestinal tuberculosis.*—A boy, aged 9 years, suffering from intestinal tuberculosis was treated with 44 injections (24·1 c c. Rosenbach's tuberculin). 1 year 10 months after the beginning of the treatment complete and permanent recovery was proved. Increase of weight in this time 7·75 kilogrammes.

Göttingen.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF TREPHINING IN ACUTE GLAUCOMA.

BY A. A. BRADBURNE, F.R.C.S. EDIN.,

HONORARY OPHTHALMIC SURGEON TO THE HYDROPATHIC HOSPITAL, SOUTHPORT; OPHTHALMIC SURGEON TO ORMSKIRK HOSPITAL AND DISPENSARY.

IN the issue of THE LANCET for Oct. 21st last (p. 1136) Mr. Sydney Stephenson describes a successful case of trephining in acute glaucoma. In the treatment of chronic glaucoma this operation is becoming more into favour and its value better known. In acute cases it is still on its trial, hence the necessity for recording cases in which its use has proved of benefit.

The patient in the present case was a single woman, aged 51 years. I saw her first in consultation in May, 1910, when she was suffering from a fairly severe attack of congestive glaucoma of the right eye. Under appropriate treatment the attack subsided, and though warned to keep herself under observation this she failed to do. On the evening of Sept. 27th I was asked by her medical attendant to see her again, and I found the patient suffering from a more intense form of glaucoma. The pain radiated mostly down the side of the neck and right shoulder-joint. The ocular symptoms were unmistakeable—semi-dilated, inactive pupil, no anterior chamber, hazy media, dilated conjunctival vessels, and plus tension with tenderness on digital pressure. The patient was immediately removed to a nursing home. Two leeches were applied to the temple, two powders of 2 grains of calomel were administered at two-hourly intervals, and a sleeping powder of trional and compound ipecacuanha was ordered. Locally dionin and eserine were instilled every hour. These measures gave marked relief, the action of the calomel being particularly copious. The bowel contents were evacuating for the ensuing 24 hours although the patient had denied any possibility of their being confined. So much for the reliability of the patient's statements. As the patient was a chronic bronchitic with marked atheroma administration of a general anæsthetic was to be avoided if possible. It was therefore decided to attempt the operation under the local use of cocaine, which seemed more feasible now that the ocular tension was a trifle lowered. Further, as the iris was lying close against the posterior surface of the cornea, the ordinary operation of iridectomy would have presented great difficulties which would not have been lessened by the hyperæsthesia of the eye.

Cocaine and adrenalin having been instilled, a flap of conjunctiva was raised and the trephine was applied over the neighbourhood of the limbus. Until the instrument came down on the ciliary nerves no pain was complained of, but when this stage was reached solid crystals of cocaine had from time to time to be placed in the cut of the trephine. As soon as the disc of sclera was removed the bottom of the wound was found to be blocked by the iris and a spatula was very gently introduced, but not without causing the patient to experience some pain, and its base was pushed back into the anterior chamber which allowed the aqueous to be slowly evacuated. This step in the procedure of allowing the aqueous to slowly leak away is an important detail when the intraocular pressure is accompanied by high arterial pressure.

Before the operation the blood pressure had been taken, and was ascertained to be 149 mm. Hg. The conjunctival flap was replaced and the wound dressed. The patient was given another trional and compound ipecacuanha powder, and she obtained a good night's rest. The tension of the eye next day was normal, and for the next three days it progressed satisfactorily. On the fourth day a slight ciliary injection came on, which was treated successfully by a weak solution of atropine for three days. The subsequent progress of the case was eminently satisfactory in every way, and when the patient was seen three weeks after the operation the vision was the same as it had been when first examined. The trephine hole was patent and acting, so as to cause the tension to be quite normal, and a total absence of pain had marked the progress of the case from the date of the operation.

The following are some of the points of interest in this case. 1. The untrustworthiness of a patient's statements as to the condition of the bowels. In this case their evacuation after calomel lasted over 24 hours, and on this a large responsibility rested for the onset of the eye condition. 2. The risks which a patient runs of being lulled into a sense of false security by the sole use of drug treatment. 3. The valuable means which the operation puts into our hands for overcoming the very great technical difficulties associated with operative interference in these acute attacks. 4. The importance of ascertaining the blood pressure immediately before operating, as on its finding depends the rate at which it is prudent to evacuate the aqueous.

Manchester.

A CASE OF HERPES FOLLOWING SPINA BIFIDA.

BY C. STEWART WINK, M.R.C.S. ENG., L.R.C.P. LOND.

THE patient was a full-term female child, born on July 4th, 1911, and labour had been normal. On examination a raw area of the size of a five-shilling piece was found in the lumbo-sacral region. This was covered by a glistening membrane on the deep surface of which the structures of the spinal cord could be seen. On the 12th (eight days after birth) a crop of herpes appeared on the right side immediately below the last rib and extending from the spine posteriorly to the midline anteriorly and limited to one nerve area. On the 14th another crop appeared in the corresponding position on the left side. The temperature remained normal throughout, but the child became more and more cyanosed and died on the 25th.

I can find no record of herpes associated so closely with spina bifida.

Halstead.

MIDDLESEX HOSPITAL.—In the annual report of this institution, which was adopted at a meeting of the Board of Governors held on Nov. 30th, it was stated that by an extensive scheme of reorganisation the capacity of the general wards of the hospital had been increased from 318 to 330 beds. The Prince Francis of Teck Memorial Fund amounted to £28,240, including recent contributions of £2000 from the directors of the Savoy Hotel, being the proceeds of a fancy-dress ball, and £1000 from Sir Charles Wyndham. The Barnato-Joel Memorial was now nearing completion, and the wards would be opened in the New Year. The capacity of the Cancer Charity would then be 90 beds, which would be reserved for incurable patients. Visits had been paid to the new laboratories by three official representatives of bodies about to erect similar laboratories; one of these was from London, one from New York, and one from Rome. The report also stated that the male cancer patients have been transferred from the Greenhow ward on the top floor of the north-west wing to the Cancer Charity, and that the Greenhow ward had been altered and equipped for the accommodation of female medical cases. This ward will in future be called "Queen Alexandra" ward.

Medical Societies.

HARVEIAN SOCIETY OF LONDON.

Some Early Signs and Symptoms in Nervous Disease.—Syphilitic Affections of Bones in Childhood.

A MEETING of this society was held on Nov. 23rd, Mr. J. ERNEST LANE, the President, being in the chair.

Dr. JAMES TAYLOR read a paper on Some Early Signs and Symptoms in Nervous Disease, which is printed on p. 1614 of this issue of THE LANCET.—The paper was discussed by the PRESIDENT, Dr. D. W. CARMALT-JONES, Mr. CAMPBELL WILLIAMS, and Dr. G. A. SUTHERLAND.

Mr. DUNCAN C. L. FITZWILLIAMS read a paper on Syphilitic Affections of Bones met with in Childhood, illustrated with lantern slides of the various conditions. He first laid stress on the fact that all syphilis was really acquired either before, during, or after birth, and that the only difference between young and old syphilitics was the difference in the want of resistance in the young, so that all the manifestations might be found jumbled up together. The different bone lesions detailed were epiphysitis (perichondritis), dactylitis, periostitis, local diffuse myelitis, and osteomyelitis. The appearances and differential diagnosis of each were entered into with the appropriate treatment. Mr. Fitzwilliams had not found many indications for "606" in children, as they were very tolerant of mercury and reacted with marvellous rapidity in the great majority of cases; he mentioned certain cases, however, in which "606" was beneficial.—The paper was discussed by the PRESIDENT, Mr. WILLIAMS, and Dr. SUTHERLAND.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

The Position of the Stomach as a Guide to Pyloric or Duodenal Difficulty.—Vaccine-therapy.

A MEETING of this society was held on Nov. 29th, Mr. J. M. COTTERILL, the President, being in the chair.

Dr. WILLIAM RUSSELL contributed a paper, illustrated with numerous lantern slides, on the Position of the Stomach as a Guide to Pyloric or Duodenal Difficulty. He said that eight years ago he had submitted a communication to the society on the subject of hyperchlorhydria in which he had dealt with the symptoms, probable nature, and treatment of the condition. Last year he had published a paper which again dealt with the subject, and he had only time now to state that hyperchlorhydria had generally come to be accepted as a definite clinical entity. He added that it was also a generally recognised fact that gastric hyperacidity was often associated with gastric ulcer; that, in fact, gastric ulcer was probably nearly always due to such hyperacidity. It seemed to him to be equally true that pyloric and duodenal ulcer were usually associated with this over-secretion—that, in fact, it was an important factor in their etiology. It was unnecessary that he should enlarge upon the question of duodenal ulcer, but stated that in his experience the perforation of acute duodenal ulcer was as rare as was the perforation of acute gastric ulcer. There was abundant operative evidence that such ulcers had healed; there was also much clinical evidence that, in favourable circumstances, they healed at least as readily as did gastric ulcers. It was important to recognise that ulcer in the stomach and duodenum was not necessarily always of equal severity; that in some cases there was certainly a considerable depth of tissue destruction, whilst in others the loss was probably much less deep, and that in the latter the process of healing must be more easily and more quickly effected. In all acute ulceration in these regions, the ideal before the clinician ought to be to obtain rapid healing. How this could best be obtained needed not to be discussed, but the axiom stated must be kept prominently in view. The reason was that where rapid healing was effected no appreciably bad results remained; whilst if healing was slow there was not only prolonged suffering, but there followed so much thickening and induration that the stomach outlet or the narrow channel beyond it became greatly diminished in calibre, with the result that the gastric contents were unduly retained. Dr. Russell had seen one case where the difficulty in the duodenum followed upon operation for perforation of a duodenal ulcer. A puckered scar either at the pylorus or in the duodenum led to difficulty in the emptying of the stomach, and this difficulty in course of time led to the changes in the position of the stomach to which he sought specially to direct attention. It seemed to him to be essential to the correct understanding of such cases as he was dealing with to keep distinctly in view the question of ulcer from the question of mechanical obstacle to the outgoing of the gastric contents. No doubt they often overlapped, but it was by realising these two distinct factors that they could hope to attain to completeness of differential diagnosis. A few years ago he had submitted to the society a paper on Congenital Pyloric Stenosis in the Adult in which it was shown that this congenital narrowing led to difficulty in the emptying of the stomach; since then he had seen one example of a pylorus situated so high up in the abdomen that it suggested the conclusion that the stomach must have always worked at a great disadvantage, and that it was no matter for surprise that the symptoms of such difficulty should have become prominent under the strain of work in early adult life. The difficulty in the emptying of the stomach was, of course, the cause of the retention of gastric contents; and it was the retention that was the cause of the symptoms. The most evident result of a difficulty to the outgoing of gastric contents was, of course, "dilatation" of the viscus. So much was universally known, but the term was much too general and vague for the purposes of differential diagnosis in this region. There was a dilatation of the fundus, there was ptosis of the body of the viscus, there was ptosis of its inferior border, and there was overlying of the pylorus by the distended anterior wall of the stomach being carried far to the right of its normal position. In all these, with the exception of the first and last, the position of the axis of the viscus in relation to its outlet was so altered that under the most favourable conditions it could with difficulty be completely emptied. Dr. Russell could not attempt to deal with more than one of these—namely, the position of what for clinical purposes he called the right border of the stomach. The methods by which the position of the stomach was determined were: visible peristalsis, percussion, succussion, and auscultatory succussion. The position of abnormal stomachs could be determined without X ray examination, although such examination was interesting and confirmatory in certain instances.

Dr. D. CHALMERS WATSON said that he doubted much if hyperchlorhydria was really a clinical entity. A single examination of the gastric contents might show an excess of acid, while at another time there might be no excess. He considered that combined percussion and auscultation was in many cases valueless, or at least of comparatively little value. There were such enormous variations in the size and position of the stomach under normal conditions that one ought to be exceedingly chary in drawing conclusions.

Dr. J. S. FOWLER asked if Dr. Russell had observed any case of dilatation of the stomach in children between the ages of 3 and 10 years, and if these were due to congenital obstruction of the pylorus. He thought the symptoms were characteristic. In one case he had found a healed tuberculous ulcer at the mouth of the duodenum. In another child, aged 6 years, there was such a degree of dilatation of the stomach that it extended into the pelvis, and the condition had persisted during three years.

Dr. G. LOVELL GULLAND said that he could reproduce an exact series of such cases as those of Dr. Russell, with, however, no question as to the presence of pyloric or duodenal stenosis in them. Hyperchlorhydria was a clinical entity, though perhaps not a disease. He agreed as to the value of percussion and auscultation in estimating the size of the stomach, and said that radiologists were not so sanguine as to the results of bismuth meals in showing the size of the stomach as was Dr. Chalmers Watson.

Professor F. M. CAIRD said that the contour of the stomach as determined clinically was often not the same as that found on opening the abdomen, but it had to be remembered that in the latter condition the organ was empty and contracted. The position of the pylorus was, however, very important, and very frequently it was found in the middle line. He thought that the position of the stomach should be determined when the patient was sitting or standing

up as well as when he was lying down. Patients were often the first to discover a neoplasm in this locality by bending forwards.

Dr. W. T. RITCHIE asked if any benefit had resulted from an examination of the stomach after inflation. Personally he preferred the simple, and to him more accurate, method of determining the size of the stomach by percussion. He also put in a word in favour of the bismuth meal in determining the size and position of the stomach. He could not rely on the results of auscultation and percussion when compared with the examination by the fluorescent screen.

Mr. H. J. STILES said that, judging from what was seen in congenital stenosis in children, he invariably found the antrum pylori passing well to the right and covering over the pylorus. He asked if as much had been described by the radiographer, and consequently he laid as much stress on the method of estimation as performed by Dr. Russell. When a stomach was filled with a bismuth meal and the patient stood up the observer did not get the true position of that viscus. It mattered not whether the patient had an obstruction at the pylorus or not, but the real test was whether he could empty the stomach. The condition might be merely atony of the stomach with dilatation, yet it required operation quite as much as if stenosis were present. In all cases, however, he thought it was necessary to close the pyloric orifice.

Dr. RUSSELL, in reply, said that a physical difficulty in the stomach emptying itself had to be overcome by physical means. None of the speakers had seemed to realise that he was describing a new method of mapping out the stomach. Percussion as one means was most valuable, for by its use one could always determine the fundus. The method he had worked out was succussion; it was only obtained if there were air and semi-fluid contents in the stomach. By means of the succussion wave one could absolutely determine the lower and right border as well as the fundus of the stomach. He had wished to direct attention to the importance of the displacement of the stomach to the right of the middle line—when the condition could not be corrected—and that this displacement was an important guide as to diagnosis and to treatment. If this displacement could not be rectified then the patient continued to suffer discomfort, and only surgical interference could benefit him.

Dr. JAMES RITCHIE introduced a discussion on Vaccine Therapy. At the outset it was pointed out that bacterial intoxications must be differentiated from the true infections, that the general bodily disturbances characteristic of the latter were non-specific, and that nothing was known of the underlying processes. In the true infections, while the escape of bacilli into the body was common, the bacterial multiplication causing the disease was essentially focal in character. The recovery from infections probably depended on some mechanism in the body being stimulated by the passage into the circulation of living bacteria or of autolysed products. The activity of this mechanism was reflected in the appearances of anti-bacterial substances in the serum which probably played an executive part in bringing to an end the multiplication of bacteria in a disease focus. The most important of these substances were bactericidal bodies and opsonins, and from the standpoint of the most common human infections the latter probably deserved most attention. The composition and standardisation of ordinary and anti-tubercular vaccines were described by the speaker. It was pointed out that vaccines contained protoplasmic material analogous to that passing into the body from a focus of infection. The injection of such a vaccine into an animal caused the development of resistance to subsequent infection with living organisms, and this resistance depended on the activity of the mechanism already referred to. Thus, if a vaccine be used prophylactically, the body fluids as a whole were rendered relatively inimical to bacterial life, so that if living bacteria subsequently gained admission they found themselves in a hostile environment. The therapeutic use of a vaccine rested essentially on the fact that bacterial multiplication was focal. Thus the injection of a vaccine might stimulate the body so that the local focus was sufficiently flooded with antibodies to kill off the invading bacteria. The sequence of events after a vaccine was introduced was discussed. Where the development of antibodies could be followed with the greatest accuracy they were found not to appear until after from 36–48 hours. During this preparatory period, which corresponded to the "negative" phase, the body might be more than usually susceptible to invasion. The object of a successful vaccination was the establishment of free antibody formation usually referred to as the "positive" phase. The essential difficulty underlying vaccination procedures was that the resources of the antagonistic mechanism of the body were, where bacterial protoplasm was concerned, exceedingly limited. The condition contrasted with what was seen in immunisation against an extracellular toxin, such as that of the diphtheria bacillus, where in an animal an immunity against many thousand times the minimum lethal dose would be easily attained. The question arose of how the effects of vaccination procedures were to be judged of so that the treatment might be followed by the maximum of good and by the avoidance of harm. It was recognised that the estimation of the opsonic index constituted the only serological method at present available for following the course of a difficult immunisation, but the laborious nature of the procedure, the impossibility of an opsonist maintaining his training without daily practice, and the question of the validity of the interpretation of opsonic results, contribute to make its use at present almost impracticable. It lies with the clinician to define with the most laborious care the signs and symptoms of the successful and unsuccessful reaction in the case of each infection. The results obtained by vaccine-therapy were then discussed. On the prophylactic side the success of antityphoid inoculation was pointed out, and it was insisted that all persons likely to be exposed to typhoid infection abroad should undergo the treatment. The difficulties of estimating the results of the therapeutic uses of vaccines were discussed. At present judgment must be based on statistical inquiries in a series of cases treated by the method as compared with a series untreated. In certain diseases some data of this kind were at present in existence. In cases where these were not available the unsatisfactory method of opinion based on limited experience was alone available. The only circumstance in which weight might be really attached to such a judgment was where a sudden improvement took place as the result of vaccination either in a chronic disease after previous treatment had failed or in an acute illness of fatal import. Certain of the results were then discussed in detail. In chronic suppurative conditions there was universal agreement that good results had been obtained, the only qualification being that the success in the treatment of acne had not been of such a striking character. Good results had also been obtained in gonorrhœal arthritis and in gonorrhœal vulvo-vaginitis in children. In the latter the success of the vaccine treatment as compared with ordinary methods was noteworthy. In tuberculosis statistics were given supporting the prevalent view that tuberculin inoculations had definitely improved the results obtained by sanatorium treatment. With regard to tuberculous glands, where caseation had not occurred, vaccine-therapy was likely to have good results, and success also attended the treatment of cases recurring after operation, of persistent sinuses, and of mixed infections. Where, however, caseation or abscess formation had occurred, these must be treated on ordinary surgical lines. In tuberculosis of bones and joints, a plea was put forward for the more extended application of tuberculin in early synovial tubercle during periods when surgical treatment by rest was being carried out, it being pointed out that in this form of tuberculosis caseation was relatively a late phenomenon. Attention was directed to the success which had attended the vaccine treatment of old-standing, semi-quiescent tuberculosis in whatever site it occurred, and it was pointed out that many apparently desperate cases of this kind had yielded in surprising fashion. In non-tubercular infections of the urinary tract good results had been obtained, especially in subacute coli infections and even in many chronic cases. Here, however, while the symptoms might disappear bacilluria frequently persisted. Passing to acute diseases, it was shown that striking success had attended vaccine-therapy in pneumonia, erysipelas, and typhoid fever. In summing up, Dr. Ritchie stated that the application of vaccine-therapy was limited—first, by the limitation of the capacity for antibacterial response in the human body; secondly, by the existence of individual peculiarities of disease manifestations; and thirdly, by the fact that they were still in the dark as to the

means to be adopted for bringing out the highest degree of antibacterial response. The essential condition favourable to the action of a vaccine was that the body fluids containing antibacterial substances must have free access to the focus of infection. The impossibility of fulfilling this condition explained the difficulties arising in tuberculosis where the bacilli were interned in caseous deposits. It also explained the difficulty of attacking bacilli which were multiplying on free surfaces of the body, as happened, for instance, in typhoid carriers. In certain cases the access of antibodies to the bacteria could be favoured by associated procedures, such as the relief of tension, &c. In this new therapeutic procedure practice was in advance of scientific knowledge, but the success attending the treatment of such conditions as furunculosis suggested that with further knowledge regarding the pathology of infection a similar success might attend the treatment of other diseases. The present situation was not final, and a definite case had been made out for further work. An essential condition was that every vaccine procedure must be looked upon as of the nature of a scientific experiment, often of a tedious character. It was essential that anyone applying the method should obtain a mastery of the underlying principles. One of the most important of these was that no hard-and-fast rules relating to dosage or interspacing of doses could be laid down. Vaccine-therapy more than any therapeutic method recently introduced had suffered from the indiscriminate use of its weapons by those who had taken no trouble to acquire a knowledge of their characters. While further specialisation in medicine was to be regretted, it might be laid down that in all serious cases where vaccination was applied special knowledge was necessary, if the best interests of the patient were consulted. There had been a tendency in certain quarters to apply vaccine treatment to disease whether or not there was any scientific ground for supposing that the condition was of bacterial origin. The empiricism of such procedures was to be utterly deprecated, and would discredit not so much vaccine-therapy as the whole practice of medicine.—Owing to the lateness of the hour the discussion was delayed until the next meeting.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Pregnant Myomatous Uterus.—Cæsarean Section.

A MEETING of this section was held on Nov. 17th, Dr. A. J. HORNE, the President, being in the chair.

Dr. GIBBON FITZGIBBON showed a specimen of Pregnant Myomatous Uterus. A woman, aged 38, married about six months, was sent to him complaining of severe abdominal and pelvic pains. From the history it was obvious that she was pregnant. She had not menstruated for almost three months. A tumour was felt extending half-way to the umbilicus, and another tumour completely filled the hollow of the sacrum. He opened the abdomen with the object of doing a myomectomy, but the tumour on the posterior wall of the uterus had so extensive a base that he thought the risk of myomectomy would be too great. Practically the whole uterus was taken out. There was a fibroid in the anterior part of the fundus, also a couple of pedunculated fibroids at each cornu of the uterus.—Dr. E. H. TWEEDY asked what Dr. FitzGibbon considered to be the cause of the pain, as myoma of the pregnant uterus did not usually give rise to pain. In his opinion it would have been possible to remove all the myoma without injury to the uterus. A point that occurred to him was, should the woman not have been allowed to go to full term?—Mr. J. S. SHEILL asked what actuated Dr. FitzGibbon in deciding to do hysterectomy at once.—Dr. H. JELLETT said that the point that arose in his mind was, not so much why the case was operated on as whether it might not have been better to take out three of the tumours and leave the patient the uterus.—Dr. FITZGIBBON, in reply, said that he thought the cause of the pain was peritonitis. The large fibroid in Douglas's pouch was slightly adherent, which might possibly have given rise to the pain. He did not see the possibility of the patient going to full time; but perhaps it might as well have been permitted with the chance of ending up with Cæsarean section. The fibroid of the posterior wall of the uterus was low down, and he did not see how it could have been enucleated safely. As the patient had particularly impressed on him that she did not want to take any risks for the sake of having a family he only felt justified in adopting the course he did.

After the PRESIDENT had read his address,

Dr. C. YELVERTON PEARSON contributed a paper on Four Successful Cases of Cæsarean Section, with Observations.—Sir WILLIAM SMYLY remarked that it was curious that they had not a greater number of Cæsarean sections in Ireland. In Glasgow they had them every fortnight or even oftener. This he attributed to the fact that Irish women nursed their children, whereas the Scottish did not.—Dr. FITZGIBBON said he thought that the first case reported by Dr. Pearson answered the question which he had asked when showing his specimen that evening. It was obvious in his case that labour could not take place past the fibroid, but perhaps it might have been left so and a section done later, as was done in Dr. Pearson's case. The point in favour of operating before labour started he agreed with. He thought the separation from the uterine wall was advantageous, as the bleeding from the mother was not increased, whereas the bleeding from the child would be diminished.—Mr. SHEILL said, with reference to the douching of the uterus in the case of uterine inertia, he thought it would be impossible to use the douche sufficiently hot to be of any value.—Dr. B. A. H. SOLOMONS said that at extra-peritoneal Cæsarean section he was struck with the advantage of only opening up the lower uterine segment, as the abdominal cavity seemed to be shut off from any septic infection.—Dr. TWEEDY said that those who had not had the chance of seeing the extra-peritoneal Cæsarean section condemned it, whilst those who had seen it became enthusiastic about it. It was an operation that could be done at an advanced stage of labour, after the membranes had ruptured, and when a case was so far advanced that classical Cæsarean section was considered unsuitable.—Dr. SMITH said that Dr. Pearson's method of performing the operation before labour came on appeared to be the ideal one. He fully agreed with Dr. Pearson in not sterilising the patients on whom he did Cæsarean section.—Dr. JELLETT said that it appeared to be fairly well established that, under favourable conditions, Cæsarean section undoubtedly stood, but that it should always, if possible, be performed before labour came on. He found in operating on cases where the patient was not in labour, while the uterus was in an absolutely atonic condition when out, as soon as it was replaced in the abdomen contraction immediately started.—Dr. GIBSON said that he had done the operation eight times, and all the cases had done well. It was, he thought, of importance that, before commencing, the patient should have an intramuscular injection of ergot. He did not see why extra-peritoneal Cæsarean section was so called, because the peritoneum was opened although sutured. Personally he never did the operation, and he did not see the advantage of it.—The PRESIDENT said that in the first case reported it was found that a large posterior myoma blocked delivery. He remembered a similar case where the patient got into labour, and as it advanced the tumour was pulled up and the woman delivered herself. It was a case in which Cæsarean section might have been done. In a case like the second one mentioned—contracted pelvis—it was always found that before labour set in the membrane was ruptured, consequently in such cases the moment the membrane ruptured a Cæsarean section ought to be done. It appeared to him the simplest operation that one could do.—Dr. WILLIAM PEARSON, who read the paper in the absence of the author, replied from the surgical point of view. In his opinion, hæmorrhage from the placenta was as likely to occur in one form of operation as in the other, and if an abdominal tumour were present it would decide which should be undertaken. From the point of view of the surgeon he would be inclined to say that the safer and better operation was the old one of opening the abdominal cavity, bringing the uterus outside.

SCOTTISH OTOLOGICAL AND LARYNGOLOGICAL SOCIETY.—A meeting of this society was held at the Royal Infirmary, Edinburgh, on Nov. 25th, Dr. J. Malcolm Farquharson being in the chair.—Dr. Farquharson showed a man, aged 72, suffering from Epithelioma of the Laryngo-pharynx, with a large growth in the right pyriform fossa, the chief interest of which lay in the

laryngeal appearance. Though there were no laryngeal symptoms there were marked redness and swelling of the left ventricular band entirely concealing the left cord, which had partly disappeared on sedative treatment. He thought the laryngeal condition due to torsion from the growth.—Dr. Farquharson also reported a case of Primary Nasal Syphilis in the floor of the vestibule of the right nostril. Fourteen days after an injection of "606" Wassermann's reaction, which had been positive, was negative, and at the end of six weeks all œdema and induration had disappeared.—Dr. G. T. Guild showed a woman on whom, eight years ago, he had performed Thyrotomy for Severe Dyspnœa in a case of Lupus of the Larynx. The result was most satisfactory.—Mr. W. G. Porter showed: 1. A case of Suspected Inflammation of the Mastoid Process illustrating the diagnostic value of a skiagram. The discharge from the ear had ceased, but œdema and tenderness over the mastoid remained; the temperature was 100° F., and leucocyte count 16,800. A skiagram of the mastoid was taken, but before it was developed the mastoid cells were opened and were found healthy. On development the skiagram showed a condition in accord with that found on operation. The general opinion in the discussion was that, while skiagraphy was of service, chief reliance should be placed on the clinical phenomena. 2. A woman with Varix involving the Soft Palate, the Left Tonsil, and the Left Pharyngeal Wall. The condition had been present for 16 years at least and caused a choking sensation, especially on stooping. The opinion of the members was asked as to treatment. Dr. A. Brown Kelly, Dr. J. W. Downie, and Dr. Farquharson referred to similar cases. Dr. Farquharson recommended electrolysis and carbon-dioxide snow, which was supported by Dr. W. Milligan. Surgical interference was deemed inadvisable. 3. A case of Chronic Pneumococcal Ulceration of the Pharynx, Tonsils, and Tongue in a boy who, when first seen in January, had small superficial ulcers and small opalescent patches not unlike mucous patches on both tonsils, even in the pharyngeal wall. The cervical glands were enlarged. Active antisyphilitic treatment failed, the ulceration continuing to spread. A swab from the throat on two separate occasions, with a month's interval, gave a pure culture of pneumococci. Twelve doses of pneumococcal vaccine were injected, and local antiseptic treatment was continued, but the disease remained uninfluenced. In September he was sent to the country. The ulceration rapidly healed and there was now no sign of recurrence.—Dr. A. Logan Turner showed: 1. A woman, aged 31, who had had a discharge from her right ear for three years, and on whom he had operated for chronic middle-ear and labyrinthine suppuration complicated by sigmoid sinus thrombosis and septic lepto-meningitis. On admission the tests pointed to involvement of the labyrinth as well as of the middle ear. Lumbar puncture gave exit to cerebro-spinal fluid under very considerable pressure, but it was not turbid. The radical mastoid operation was followed immediately by double vestibulotomy, and the internal auditory meatus was opened, permitting the escape of cerebro-spinal fluid. Three days later the internal jugular was tied and the lateral sinus opened. The fluid from the sinus gave a diplococcus resembling pneumococcus and bacillus proteus; the cerebro-spinal fluid streptococcus pyogenes and staphylococcus albus; and that from the mastoid bacillus proteus and streptococcus pyogenes. Vaccines of the streptococcus and of the bacillus proteus were given on alternate evenings—ten doses in all. The patient improved, but again relapsed, the symptoms of meningitis reappearing. Lumbar puncture was performed on several occasions, and as the streptococcus had disappeared from the spinal fluid a staphylococcus vaccine was given daily. After six weeks the patient made a complete recovery. Dr. Adam, Dr. Milligan, Dr. J. Stoddart Barr, and Dr. W. S. Syme discussed the case. 2. A man, aged 53, one year and eight months after Thyrotomy for Epithelioma of the Right Vocal Cord and the Anterior Third of the Left. The man could only speak in a whisper, but there was no sign of recurrence. 3. A boy, aged 7, from whose right bronchus Dr. Turner had removed a toy metal pipe by direct upper bronchoscopy under chloroform.—Dr. Milligan showed a large pebble which he had removed from the bronchus of a man by a similar method.—Dr. Logan Turner and Dr. J. S. Fraser showed (1) a patient with Ulceration of the Palate with pus and granulations in the right nasal cavity; and (2) a patient with a large Swelling of the Left Ary-epiglottidean Fold, with signs of congenital syphilis. In both cases von Pirquet's reaction was positive and Wassermann's was negative, but the condition in both was thought to be specific.—Dr. Fraser gave a lantern demonstration of Injury to the Ear in two cases of Fracture of the Base of the Skull.—Dr. Fraser and Dr. J. K. Milne Dickie contributed an analysis of 123 consecutive cases in which operations were performed for the relief of the mastoid, labyrinthine, and intracranial complications of suppurative middle-ear disease. The analysis of these 123 cases was very full and interesting and gave rise to a prolonged discussion. Dr. Fraser and Dr. Dickie were specially thanked.—Dr. J. Kerr Love showed: (1) a Brain and stereograms illustrating a case of Temporo-sphenoidal Abscess; and (2) stereograms of a case of Malignant Disease of the Auricle, Parotid Gland, and Pterygoid Fossa.—Dr. Logan Turner and Mr. Porter gave an interesting demonstration of skiagrams of cases of Naso-antral (Choanal) Polypus, cases of Dental Cyst, and a case of Mucocele of the Frontal Sinus. They also showed Stereoscopic Views of the Skull.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 24th, Mr. H. Littlewood, the President, being in the chair.—Dr. C. Oldfield read a paper on the Treatment of Uterine Displacements. He maintained that not one of the uterine displacements of itself produced symptoms, and therefore that treatment should not be directed to rectifying the position of the uterus, but to curing the accompanying condition which produced the symptoms. The reasons given for holding the opinion that *backward* displacement of itself causes no symptoms were: 1. To find backward displacements without symptoms was a common clinical experience. 2. When symptoms did accompany this position of the uterus some pathological lesion could usually be found on careful physical examination to explain the symptoms. 3. In some cases where no pathological lesion could be found, the patient could be cured without disturbing the position of the uterus, e.g., dysmenorrhœa and sterility. In other cases where no pathological lesion was made out, exploration of the pelvis by the abdomen revealed a cause, such as general adhesions of the pelvic viscera with chronic inflammatory disease of the appendages. Sometimes no lesion of any kind was found even on exploration, but most of these cases, if not all, belonged to the class generally called "neurotic." The inferences drawn from these observations were: 1. That the use of the pessary in the treatment of conditions where the uterus was found lying in a backward position must be very limited. 2. That a suspension or other operation for *uncomplicated* backward displacement was unnecessary and may be harmful. The results of operations for "prolapse" were given. During the five years from March 1st, 1906, to March 1st, 1911, there were 98 operations, with no deaths; 45 came for examination recently, and of these 3 showed recurrence, 2 of small cystocele without symptoms, and 1 (an old woman, 66 years of age) with complete recurrence. Twenty-three others, in reply to letters of inquiry, complained of no recurrence.—Dr. Leonard A. Rowden showed five cases of Rodent Ulcer treated in the following ways: (1) Entirely by radium; (2) entirely by "secondary" radiations; (3) chiefly by "secondary" radiations and partly by radium; (4) and (5) by "primary" radiations and radium combined. Complete recovery occurred in all cases except in (3), in which only a very small area still remained unhealed.—Mr. H. Secker Walker showed two cases of Chronic Glaucoma treated by Herbert's operation, and explained the details of the operation, pointing out that there was no subsequent disfigurement of the eye, that it was useful in both acute and chronic cases and was probably the most trustworthy of any of the glaucoma operations at present before the profession.—Mr. J. F. Dobson showed a specimen of Tuberculosis of the Kidney.—The President showed a female patient, aged 47 years, whom he had successfully operated on for gangrenous pancreatitis. Her symptoms were very severe pain in the right hypochondrium with vomiting. At the operation multiple fat-necroses were seen, and also a sloughing condition of the head of the pancreas. Some small sloughs were removed and a drainage-tube was inserted into the sloughing area. 130 gall-stones were removed from the gall-bladder, which was drained. The urine gave the pancreatic reaction.—Dr. W. H. Maxwell Telling and Dr. D. Wilson showed a patient, aged 27, with Spondylitis Deformans. The onset

had been an insidious one five years previously, with increasing stiffness and pain in the spine. There had also been a certain amount of stiffness in various joints. At the present moment the upper part of the spine was quite rigid and slightly flexed at the cervico-dorsal junction. There were well-marked chronic fibro-arthritic changes in the right knee.—Dr. Oldfield showed a case of Pubo-sacral Hernia, in which the uterus and bladder were in normal position. The patient had had complete "procidentia" for 20 years or more. A year previously carcinoma of the cervix developed, and the broad ligaments became infiltrated with growth, from the contraction of which the uterus and bladder had become drawn up into their normal position.—Mr. H. Collinson showed a uterus containing large Degenerating Fibromyomata. The patient was four months pregnant, and the uterine walls were of extreme thinness. Abdominal hysterectomy was performed, with recovery.—Other cases and specimens were shown by Dr. A. G. Barrs, Mr. W. Gough, Mr. H. J. Roper, and Dr. T. Wardrop Griffith.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 24th, Dr. A. Freeland Fergus, the President, being in the chair.—Dr. J. Goodwin Tomkinson showed a case of Nævus Verrucosus and several cases of Lupus Erythematosus under treatment with solid carbon dioxide; a case of Multiple Keloid and cases of Extensive Rodent Ulcer under treatment with X rays; cases of Lupus Vulgaris under the combined treatment of X rays and cauterisation; and several children whose scalps had undergone complete X ray epilation for Tinea Tonsurans and now exhibited complete re-growth of healthy hair. He considered X ray epilation a perfectly safe method in the hands of a careful operator, and the only dependable one in the treatment of tinea tonsurans.—Dr. John Brownlee made a few remarks on Spinal Affections following Enteric Fever, and recorded an interesting case. The patient had developed, when aged 15, a lateral curve of the spine, but had been practically well and able for hard machine work until, at the age of 32, he contracted enteric fever. This attack was very severe, the temperature not reaching normal till the thirty-fifth day. A month later he developed thrombosis of the left leg. During convalescence from this symptoms suggesting syringomyelia developed; the sensation of pain was practically absent from the middle of the thighs downwards; heat and cold could not be distinguished; plantar reflexes were much exaggerated, and ankle clonus and Babinski's sign were present. These symptoms became worse, until the disturbance of heat sensation and loss of pain sense were present up to the lower costal margin; the sensation of touch, however, was nowhere lost. From this point he made a very slow but uninterrupted recovery, and at the end of 21 months was able for a hard day's work, and had heat and pain sensation present all over the body, though these sensations were delayed over the dorsa of the feet and the lower third of the legs.—Dr. Archibald Young described three unusual cases of Dislocation of the Metatarsus at the Lisfranc Joint. In two cases the whole metatarsus was displaced outwards, and in one of these there was also moderate dorsal displacement. Both showed some comminution of bone at the joint between the cuneiforms and base of second metatarsal. In both an accident had caused violent adduction of the tarsus, while the anterior part of the foot was fixed. In the third case the first metatarsal was displaced inwards, while the second, third, and fourth metatarsals were displaced outwards and on to the dorsum, and showed some comminution of their bases. The patient had fallen from a height, and the injury resulting suggested that the tarsus had acted as a wedge, the apex of which was formed by the internal cuneiform. In all three cases the diagnosis was easy; reduction was accomplished without difficulty under an anæsthetic; the foot was fixed in plaster for three weeks, and the anatomical and functional results were entirely satisfactory.—Dr. Alexander MacLennan described an Anatomical Method of Enlarging the "Gridiron" Incision, with special reference to removal of the retro-cæcal appendix. After splitting the external oblique, the rectus sheath was to be cut transversely at a level corresponding to the insertion of the fibres of the internal oblique which arise from the crest of the ilium, a finger's breadth above the anterior superior spine. The split was continued outwards to the iliac crest. Further enlargement was obtained by cutting the origin of the internal oblique and transversalis muscles from the crest. In this way the upper part retained the ilio-hypogastric for its innervation, and the lower retained the ilio-inguinal. The fascia and peritoneum were cut on the same line. Thus an extensive view could be obtained of the ascending colon and the appendix hidden in its mesentery. The outer layer of the colic mesentery was then divided by scissors and the appendix removed. The closure was accurate and easy. The method was illustrated by drawings by Dr. William Mackie.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 1st, Mr. W. McAdam Eccles, the President, being in the chair.—Dr. Seymour Taylor read a paper on Unrecognised Diphtheria. He said that in diagnosis of doubtful cases one might easily arrive at a wrong conclusion, especially in diphtheria, in which there was no rash or exanthem to guide one, and the false membrane might be situated so as to be invisible, or it might even be absent. The difficulty, therefore, arose chiefly in those cases of diphtheria with simple sore-throat without any of the confirmatory concomitant signs of false membrane, enlarged cervical glands, or of albuminuria. The following illustrative cases were related. 1. A man complained of choking and difficulty in swallowing. He had a nasal intonation, absence of knee-jerks, and palate reflex. No history of sore-throat could be obtained, until after persistent inquiry it was found that he had had a mild sore-throat three months previously. This was called to mind by a ship-mate who had suffered from a similar affection, and at the same time—namely, when both were engaged in cleaning out some part of the ship from decomposing refuse. 2. A woman complained of weariness and dyspnœa. She had paralysis of the right side of the face; no patellar and no palate reflexes. A history of sore throat could not at first be obtained. Later it transpired that both she and another woman had had sore throats shortly after the clearing of an obstructed and offensive drain. Other similar illustrative cases of mild and neglected sore throats followed by palsy of muscles and other signs of toxic peripheral neuritis were given. Attention was drawn to the clinical fact that the chief danger of overlooked diphtheria was the possibility of subsequent paralysis of the heart muscle, and cases were described bearing on this fact. It was urged that a skilled bacteriologist paid by the State should be available so that every case of suspicious sore throat could command his services. Swabs should be taken, not only from the fauces, but also from the inferior nasal meatus, and it was concluded by Dr. Taylor that a patient could not be certified as free from diphtheria unless and until two separate swabbings at one week's interval had been made and showed an entire absence of the Klebs-Loeffler bacillus.—Dr. Julius Bernstein dealt with the bacteriological aspects of diphtheria. He considered the most serious difficulty arose from the existence of healthy carrier cases, who might harbour virulent organisms to the possible danger of the community.—The President said that Dr. Taylor's paper raised questions of great importance. He would be interested to hear opinions on certain points. How soon after possible infection could the bacillus be found? What was the best area from which to take a swab? Were there such organisms as "pseudo-diphtheritic bacilli"? What was the longest time true diphtheria bacilli had remained in the throat of a carrier?—Dr. F. G. Crookshank said the practitioner's first duty, if he suspected diphtheria, was to give antitoxin. The medical man who first gave antitoxin safeguarded *his* patient; he who took a swab and waited safeguarded himself only.—The discussion was continued by Dr. G. C. Crichton, Dr. A. Ogier Ward, Mr. B. M. Bond, Dr. E. A. Saunders, Dr. Rickman Lloyd, Dr. Grainger Stewart, Inspector-General R. Bentham, and Dr. F. E. Fry.—Dr. Taylor replied.

CLASS FOR MOTHERCRAFT, BRIGHTON.—The Brighton education committee at its meeting on Nov. 28th approved of a new class for mothercraft at the evening schools. This step has been found necessary owing to the fact that the rearing and bringing up of infants is so little understood among many of the working classes; and further, in consequence of the infantile mortality which is much greater than it ought to be in the town.

Reviews and Notices of Books.

Die Experimentelle Bakteriologie und die Infektionskrankheiten, mit besonderer Berücksichtigung der Immunitätslehre. (*Experimental Bacteriology and Infectious Diseases, with Special Reference to the Theory of Immunity.*) By Dr. W. KOLLE, Professor of Hygiene and Bacteriology in the University of Berne, &c., and Dr. H. HETSCH, Staff-Surgeon in the Berlin War Office. Third enlarged edition. In two volumes. Vol. I., pp. 1–496; Vol. II., pp. 496–968. Berlin and Vienna: Urban and Schwarzenberg. 1911. Price each vol., 30 marks; bound, 34 marks.

PERHAPS the most concise general title for the contents of these two large volumes would be "A Treatise on Microparasitology," as will appear from the following summary of their contents.

The first 14 chapters, or lectures as they are here called, deal with the general principles of infective diseases, especially those due to bacteria. Thus after an introduction on the use of the microscope, we are initiated into the morphology and biological characters of the bacteria. The means of destroying them, the mechanism of infection, the methods of resistance afforded by antitoxins, agglutinins, and so forth, are next discussed, as well as the nature of anaphylaxis, and the general principles of serum diagnosis and treatment. The different infective diseases of man and animals are then considered in turn, anthrax, cholera, and typhoid fever each having a chapter to itself, and one being devoted to paratyphoid infections and flesh poisoning. Bacillary dysentery is dealt with in Chapter XIX., and the one following is devoted to bacterium coli commune and intestinal bacteria. Plague, staphylococcal disorders, Mediterranean fever, and epidemic cerebro-spinal meningitis are next discussed in separate lectures, followed by gonococcal, streptococcal, and pneumococcal affections. Chapters devoted to tetanus, malignant œdema, influenza, leprosy, actinomycosis, and glanders bring the first volume to a conclusion.

The second volume opens with lectures on diphtheria and on tuberculosis, followed by others on botulism, on soft chancre and Ducrey's bacillus, and on affections due to bacillus pyocyaneus. The three next lectures are devoted to a series of epizoötics—chicken cholera, hog cholera, swine fever, and swine erysipelas—bringing the established bacterial diseases to an end. Chapter XLII. deals with spirochætæ and the maladies due to them, syphilis being dealt with separately in the following chapter. A discussion of the general characters of protozoa occupies Chapter XLIV., and amœbic dysentery is dealt with in Chapter XLV. The next 40 pages are occupied with a single lecture on diseases due to flagellates, including the various trypanoses and kala-azar. After a short section on coccidial disease we are introduced to the subject of malaria in Lecture XLVIII. and to the piroplasmoses in Lecture XLIX. The following five chapters are devoted to diseases due to undiscovered organisms—rabies, foot-and-mouth disease, rinderpest, small-pox, and yellow fever; and Lecture LV. to the hyphomycetes and blastomycetes. Three sections are concerned with animal parasites belonging to the metazoa—ankylostoma, trichina, and filaria; and the last lecture deals shortly with other diseases of unknown causation, such as measles, scarlet fever, rheumatism, and so forth. An appendix reviews methods of cultivation, staining, and microscopical preparations in general. There is a fairly adequate index.

Detailed criticism of so large a book is impossible. However, its very comprehensiveness suggests the question why a few parasites are omitted when so many are included. Of human parasites there remain only the tape-worms and a few round worms, a few words on which would have made the work a complete treatise on parasitology. For the general treatment of the subject dealt with we have nothing but praise; the descriptions are clear and adequate, and the illustrations are numerous and for the most part excellent, many of them being in colours. The authors' views are throughout sane and moderate, and due weight is given to clinical phenomena as opposed to laboratory methods, as, for example, in the advice as to vaccine treatment and estimations of the opsonic index. Here and there we have thought the treatment of some subjects rather slight, as, for instance, that of the nature of fever and of the incubation period in infective diseases, in which latter something more is almost certainly involved than mere multiplication of the bacteria. The account of intestinal bacteria and their influence on health is also scarcely adequate; no mention of Herter's work is made. The advantage of using the term "lectures" instead of chapters is not clear, since a lecture is conventionally a discourse of about an hour's length, whereas in this book the sections vary from one of two pages on Ducrey's bacillus to one of some 50 pages on tuberculosis. In the latter we are struck by the very slight weight attributed to hereditary disposition in this disease, a factor which the authors merely hold to be "not entirely to be disregarded." We note that the spirochætæ are not here classified with the protozoa, as was done by many of the earlier writers on these organisms. In this section it is worth noting that Vincent's angina is attributed to the action of the bacillus fusiformis alone, the accompanying spirochætæ being regarded as non-pathogenic. Of minor slips we notice one sentence (alle Bemühungen ..... erfüllen) repeated word for word on pages 271 and 278, and it is a little surprising to find Homer mentioned in a list of "old Roman writers." But it is an ungrateful task to pick holes in a work of such merit. We observe that the book has already been translated into French, Italian, Spanish, and Russian, and as we know of none in our own tongue equally comprehensive and valuable we hope that it may also appear in English or American garb. Meanwhile, we advise any of our readers who wish to purchase the book to secure the bound edition, as the attempt to read the ill-sewn paper-covered volumes which fall to pieces directly they are opened is productive of acute mental exasperation.

Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India. No. 49. *Dysentery and Liver Abscess in Bombay.* By Major E. D. W. GREIG, M.D. Edin., D.Sc., I.M.S., and Captain R. T. WELLS, M.A., M.B. Glasg., I.M.S. Calcutta: Superintendent Government Printing, India. 1911. Pp. 78. Price 2 rupees, or 3*s.*

THIS volume of the Scientific Memoirs contains an admirable account of some of the factors in the causation of dysentery in India. It includes, amongst other points, the systematic working out of the material sent to the laboratory—viz., stools, pus from liver abscesses, and blood for Widal reaction; the examination of the various strains of the bacillus dysenteriæ isolated and the investigation of the amœbæ found in the liver pus and stools. During this investigation it was found that whenever there were a number of cases of dysentery associated with amœbæ in Bombay the number of cases of bacillary dysentery was small. Thus two tables are given showing the total number of cases of dysentery examined amongst the civil and military population, European and Indian, and the presence or absence of amœbæ or dysentery bacilli in the stools. The results were as follows: of 164 cases of dysentery examined amongst the Europeans, in 83 cases amœbæ were found, but the bacillus in only 3 cases; in similar manner,

amongst 390 cases among the Indians there were 198 cases of amœbæ and only 10 of bacteria.

The general conclusions arrived at are that the incidence of bacillary dysentery in Bombay is low, and that the disease is more frequently associated with amœbæ; that the latter can be cultivated from the stools and pus of liver abscesses; that the amœbæ showed a marked seasonal variation; and that their greatest prevalence corresponds to the season of greatest prevalence of dysentery in Bombay.

The authors also find that the amœbæ cultivated from the stools of dysentery cases and pus of liver abscess cases are not entamœba histolytica or coli, but are probably the same (or similar) forms of amœbæ as those cultivated by Noc from dysentery and liver abscess cases in Cochin China. Two of the most important points determined are:—Firstly, that a moderate leucocytosis, with little alteration in the relative percentages, may occur in slight cases of amœbic dysentery, or in cases where at the time of examination no symptoms of dysentery exist. This, associated with rise of temperature, may indicate an early hepatic invasion by amœbæ, which will, sooner or later, culminate in the grave complication of abscess of the liver. Secondly, it is pointed out that the administration of ipecacuanha, as shown by Major Leonard Rogers, I.M.S., will in this class of cases reduce the temperature and leucocyte curves to normal, and prevent the formation of liver abscess. This administration of ipecacuanha was urged years ago by the late Professor W. Maclean, at Netley, in the treatment of acute hyperæmia of the liver.

This number is certainly in its teachings one of the most fruitful of the Memoirs that have yet appeared, and is worthy of perusal by all who are accustomed to meet cases of dysentery.

The Mechanical Factors of Digestion. By WALTER B. CANNON, A.M., M.D., Professor of Physiology, Harvard University. Illustrated. London: Edward Arnold. 1911. Pp. 227. Price 10*s.* 6*d.* net.

THIS is the first of a series of "International Medical Monographs" which are to be issued by Dr. Leonard Hill and Dr. William Bulloch acting as general editors. This monograph is, we think, most appropriately dedicated to the memory of the late Professor Bowditch, of Harvard University—a charming personality—under whose inspiration the researches recorded in it were begun. The monographs are intended to deal with subjects of immediate interest, and to be by first-hand authorities who have been engaged in extending the confines of knowledge. All readers of the *American Journal of Physiology* are conversant with Professor Cannon's studies on the mechanical factors of digestion as revealed by means of the Roentgen rays—a department of physiology which he has initiated and extended as well as adorned by the discovery of many new facts. Every medical man will be interested in the book because it deals in a masterly manner with a subject which is of the first importance in practical medicine.

Hitherto of the two general and intimately related factors of digestion—the chemical and mechanical—the former has been more assiduously studied. It would be difficult to cite a better example of the practical rewards to be obtained from the application of a new method than that obtained by the combined use of the bismuth method and the X rays. The sensitiveness of the alimentary canal to operative procedure has been one of the chief difficulties in past investigations of the digestive process. The stomach and intestines are energetically active during digestion and are prone to cease their activities suddenly when the abdomen is opened, a change aptly likened by Meltzer, of New York, to the hush that falls upon a company when a stranger appears at the door. Even Johannes Müller stated that he had never seen clearly the peristaltic movements of the stomach. Now the writing, if not on the wall, can be seen on a fluorescent screen.

The author treats in succession the Movements of Mastication and Deglutition. The pressure exerted by the molars as determined by a spring dynamometer may be as high as 270 pounds. In this connexion we do not find a reference to the observations of Alfonso Borrelli in his work "De Motu Animalium." The author found no evidence of the contraction of the œsophagus in three sections in the act of deglutition as described by Kronecker and Meltzer. The Nervous Control of Deglutition is next dealt with. This is a wide subject, and the author gives an excellent summary as well as a criticism of previous work. He states that the general conclusion that the entire œsophagus is put out of action by section of the vagi must be modified. The part of the tube composed of smooth muscle is capable of quite perfect peristaltic activity without the aid of extrinsic nerves. In the bibliography appended to this section we failed to notice a reference to Ranvier's work on the structure of this "food-carrying" tube. The author passes on to consider the Conditions affecting the Activities of the Cardia—a sphincter which normally is chiefly responsible for the pleasant security which keeps us unconscious of the nauseating odour and highly disagreeable taste of the gastric contents. Intracardiac acidity has a marked effect on the closure of the cardia. Its effect in stopping rhythmical regurgitations of fluid from the stomach into the œsophagus can be recorded graphically. The "acid closure of the cardia" is obviously of practical importance.

The Movements of the Stomach are next considered, and a full account is given of the function of this organ acting as a reservoir, and of mixing and propelling the food, as performed by different parts of the organ—the double function that is cited in every text-book on physiology. What was not revealed to the eyes of Johannes Müller can now, thanks to the bismuth and X ray method, be made visible to every student of medicine. He can see the continued uninterrupted peristalsis until the stomach is swept clear of its contents—2300 waves passed over the pylorus during a single digestive period in a cat, and all the cat had had to eat was 15 grammes of bread! In discussing the Effects of Stomach Movements on the Contents the author states that during a single digestive period the body of the stomach may contract from a large conical sac, many centimetres in circumference, to a narrow tube little larger than a loop of intestine, and that during this alteration the pressure remains practically uniform. The left and right half of the stomach have quite distinct functions—peristaltic waves are present in the right and absent in the left half. Next the Stomach Movements in Relation to Salivary Digestion and Gastro-enterostomy are considered.

The chapter on the Passage of Different Foodstuffs from the Stomach, a subject popularised by Beaumont, is one that must interest all physiologists. The wound of Alexis St. Martin helped humanity indeed. Proteins take much longer than certain carbohydrates to pass the pylorus—a circumstance which can be explained by the remarkable mechanism of the pyloric sphincter and its "acid control," which is next dealt with, and is regarded by the author as "one of the most remarkable automatisms in the body." The pylorus is truly a "janitor justus," and makes the relation between gastric and intestinal digestive processes orderly and progressive. The account of the whole mechanism reads more like a romance than the story of a prosaic every-day humble function. The Movements of the Small Intestine—itself the very centre of the essential

activities on which the body depends for nourishment—are discussed in an attractive fashion. The Movements of the Large Intestine as they can be seen and observed in carnivores and herbivores are described. Zoologists will be grateful for this clear study. From another point of view the author makes this emphatic and practical statement, applicable to all men and often—too often—neglected by women: "The importance of responding as soon as the desire to defæcate arises is shown by the observation that the rectum accommodates itself to the presence of a fæcal accumulation, and then does not produce the desire. If the signal is not soon obeyed it ceases to be given."

We have said enough to show how attractively and practically the author has dealt with a subject of primary importance. The old physicians spoke of the "primæ viæ" without knowing much of the potentialities of their walls. On the whole they were right, and Professor Cannon has arisen to justify their faith. Student and practitioner alike can here read and follow the weighty truths as revealed by one who knows fully and writes well. The practitioner will see at once the importance of the practical application of the teaching. We thank the author and the editors for their work, and in congratulating the latter on their first "issue" hope that they will continue in their well-directed discrimination.

Thoughts of a Catholic Anatomist. By THOMAS DWIGHT, M.D., LL.D., Parkman Professor of Anatomy at Harvard. London: Longmans, Green, and Co. 1911. Pp. 243. Price 3*s.* 6*d.* net.

THIS is a rare book in the sense that any writing which reveals a thinking man's most carefully weighed and yet most intimately sacred thoughts must be rare. Few men have so painfully and so conscientiously cross-examined themselves as Dwight has, and fewer still have undertaken the criticism of their own thoughts armed with so deep a religious conviction and so sound a scientific knowledge. Being a Catholic, and having a real and fervent belief in all the tenets of his religion, he viewed with dismay a host of modern tendencies the very conception of which came so gradually and so naturally into the lives of younger men that they are passing to-day uncriticised.

To many of this generation has come a tacit acceptance that the great struggle of "science" and religion is done with; that evolution is beyond dispute; that its happenings are so certain that it has become almost as much an object of "faith" to them as religion itself is to others. This easy acceptance was never given by Dwight; for the younger men the struggle might seem ended, but to him, as he lived through all the phases of its progress, no such mental peace ever came. His early anatomical career was nurtured on the "archetype," which from being at first a fascinating idea ultimately became a horrid nightmare to him. Such a spectre did it develop into at the hands of Owen that the new views of Darwin, which seemed so definitely to slay and bury it once and for all, were hailed with delight; and Dwight confesses that he could have "danced on its grave." He watched the Darwinian views take root and grow; he marked every incident of the great struggle, and the common acceptance of a final victory; and he realised that the ghost that was laid was as nothing compared to the fiend which had issued from its grave. The archetype was a puzzle and a nuisance; but the new views were aiming a death-blow at "the only things that matter." Dwight watched the course of public opinion, he saw the pendulum swing over till any and every dogma issued in the name of the new science was eagerly swallowed whole and accepted as final, without any investigation of its merits or its truth. He saw with dismay the last phase, in which he charges the scientific world with having given dangerous and unproven theories to masses too weak to weigh and too ready to believe; and with having created a disastrous and widespread disregard of religion and morality.

For him there was no explaining away of deeply rooted belief by "the slang which in biology is allowed to pass for argument," and no acceptance of the findings of all those hasty investigators who so eagerly overhauled the body of man in search of traces of the monkey. With some of them he joined battle, and by long and patient researches into the numerical variations of the spinal column he destroyed all belief in the too readily accepted teaching of Rosenberg that the vertebral column of man was progressively tending to shorten by the forward migration of the pelvic girdle. Man, with his reason, his knowledge of right and wrong, and above all his soul, could never in Dwight's judgment be imagined as a glorified higher ape; that he had once been something higher, and not something lower, was the only possible solution of the problem of his origin.

The book in which these thoughts are given to the world is one that the reviewer feels it wrong to submit to any critical analysis, for there is in it the impression that it is the well-considered outcome of very deep, and often very painful mental struggles. The thoughts of Thomas Dwight, though they may not be submitted to the dissection of the critical reviewer, are those that must interest, and do good to, everyone who is engaged on any branch of the great study of mankind.

Transactions of the Medico-Legal Society for the Year 1910-1911. Edited by DIGBY COTES-PREEDY, M.A., LL.M. Cantab., L.S.A. Lond., Vice-President of the Society, of the Inner Temple and Oxford Circuit; Barrister-at-Law. Vol. VIII. London: Charles Griffin and Co. Pp. 184.

THE annual report of the Medico-Legal Society contains, as usual, some excellent papers and notes of discussions upon various topics of the nature indicated by its title. They are topics which, outside the walls of the society's meeting-place, bring individual members of the two professions of medicine and law into conflict quite as often as into association, and, moreover, are generally of public as well as of professional interest. Indeed, members of the Legislature might usefully join the society and learn from those whose knowledge of their subject is derived from personal observation and practical experience how much there is that needs consideration and revision in many Acts of Parliament that are left to remain from year to year unamended. For example, at a meeting recorded in the present volume a great deal might have been learnt from experiences related by Dr. R. J. Collie and others as to the disastrous effects produced in some instances by the Workmen's Compensation Act. The fact that in every year a very large number of workmen receive compensation for genuine accidents and for conditions undeniably existing and arising out of those accidents, and that the relief thus afforded is very valuable to its recipients, does not excuse the fact that in other instances fraud is perpetrated freely, and that the State does nothing to prevent or to punish a form of criminality for the creation of which it is responsible.

Legislators to whom we have specially referred will find equally instructive matter for their perusal in two or three of the other papers before us—Can the Abuse of Drugs be Prevented by Law? (Mr. Wippell Gadd) and Secret Remedies and Patent Medicines (Dr. F. W. Tunnicliffe) may be mentioned. The undignified antiquity of some of the Acts which we find governing us when we look into such a question as the stamp duties on medicinal compounds would alone suggest the need for reconsideration of the whole topic in the light of modern scientific knowledge and of modern interest in the public welfare. The history of the

law and practice connected with the ancient office of coroner has recently been the subject of direct inquiry for the information of Parliament, but there has been no legislative sequel to the departmental committee's report, and the lights and sidelights thrown on the subject by Dr. Wynn Westcott and Dr. F. J. Waldo are therefore still of potential value to anyone who wishes to master a subject which we all hope to see dealt with by the Government before long.

"Blood-tests" is the title of a paper which should be found instructive by advocates practising in criminal courts in which these are the subject of evidence, and the presidential address of Sir John Tweedy upon the "Deterrent Influence of Social and Legal Restrictions on the Medical Thought and Practice" again deals with a topic of public as well as of professional and medico-ethical interest.

Handbuch der Technik und Methodik der Immunitätsforschung. Herausgegeben von Professor Dr. R. KRAUS in Wien, und Dr. C. LEVADITI in Paris. Erster Ergänzungsband. Mit 14 Tafeln, 8 Kurven, and 17 teils farbigen Abbildungen im Text. Jena: Gustav Fischer. 1911. Pp. 664. Price, paper, M.24; bound, M.26.50.

RESEARCH in connexion with the complex problems of immunity is proceeding with remarkable activity in all civilised countries. The two volumes of Professor Kraus and Dr. Levaditi's well-known handbook gave as exhaustive an account of the practical aspects of the subject at the time they were published as was practicable. The editors state in their preface to this, the first supplementary volume, that it is their intention to issue yearly similar volumes. The size of this one gives some indication of the amount of work which has been done upon various aspects of immunity and affords the best demonstration of the necessity for such publications, since the matters dealt with are all of importance and have all been the subject of noteworthy work. It contains 25 separate articles, some dealing with more or less abstruse problems in connexion with various details of the immunity reactions, others with more directly practical questions, such as the use of specific serums and vaccines. We briefly refer to some of them.

Dr. M. von Eisler describes some of the new methods of obtaining more virulent toxins from the tetanus bacillus, and the use of serums obtained therefrom. Dr. R. Doerr gives an account of dysentery toxin and antitoxin. He states that it is generally accepted that only the Shiga-Kruse variety is to be regarded as toxic, and that the nature of the corresponding serum is antitoxic. Dr. Salimbeni discusses cholera toxins and antitoxins, and describes the results obtained with serum treatment in the Russian epidemic of 1908–1909. The subject of meningococcus serum is fully dealt with by Dr. St. Baecher, and the uses and results of the various forms are described. Professor Sobernheim deals with the preparation and mode of employment of anthrax serum. Dr. B. Schick contributes an interesting article on the intracutaneous estimation of diphtheria antitoxin, a method by which much smaller quantities of antitoxin may be titrated.

Dr. C. Levaditi, one of the editors, contributes an important review of phagocytosis and the opsonins, and describes the technique of the preparation and use of vaccines after Wright's methods. Professor C. von Pirquet gives an interesting summary of the various local tuberculin reactions. The complex question of anaphylaxis with its recent developments is discussed at considerable length in two separate articles, the first by Dr. A. Besredka, the second by Dr. A. Biedl and Dr. R. Kraus. Several of the articles are devoted to a consideration of various phases of the problems of immunity in tuberculosis. Professor Paul Römer discusses the action of the bovovaccine of Behring and of similar attempts to induce immunity, and Dr. E. Löwenstein describes fully many of the modifications of tuberculin, and gives details as to the results obtained with them. He also contributes an article on antibodies in tuberculosis, in which their nature and diagnostic applications are considered. The various serums that have been introduced for the treatment of tuberculous disease are also described and discussed. Professor H. Vallée deals with the results of cutaneous and conjunctival reactions with tuberculin in cattle. Other articles are devoted to the diagnosis of glanders, the treatment of rabies, the exciting cause of vaccinia, and the serum reactions from malignant tumours. There is also an important description of the technique of the investigation of acute poliomyelitis by Dr. K. Landsteiner.

Each article has a full bibliography attached to it, and many of them are illustrated by diagrams or plates. The book is a valuable addition to the literature of immunity and is indispensable for a fully-equipped bacteriological laboratory.

LIBRARY TABLE.

Medical Education and Infant-feeding: An Impeachment and a Suggested Remedy. By D. HASTINGS YOUNG, M.B., Ch.M. Edin. London: George Routledge and Sons, Limited. 1911. Pp. 120. Price 2*s.* 6*d.*—This little book directs attention to a matter which certainly deserves the earnest consideration of the General Medical Council, the Colleges, the Universities, and other bodies concerned in the education of the rising generation of medical practitioners. No one, we imagine, would deny that among the most urgent questions in medical progress at the present moment is that of infant mortality. Queen's College, Belfast, is the only medical school that demands and makes compulsory a course of instruction in infant dietetics. At the present moment all public ordinances as to the management of infants rest in the hands of medical men, and the public medical service, splendidly served as it is, is none the less composed of medical men without extensive clinical experience. Dr. Hastings Young calls attention to the position which results. There can be no doubt that the methods of infant feeding require unification, as Dr. Sidney Davies, medical officer of health of Woolwich, has pointed out. There is no uniformity between the directions given by one authority and possibly by another situated geographically next door to it. This causes endless confusion and want of confidence. Dr. Hastings Young suggests that Dr. Truby King's method for preparing modified or so-called humanised milk, which has been extensively used in New Zealand, should be universally adopted. This, to our mind, is quite an unpractical suggestion. The method is not a good one, and is even more complicated than the original method of Professor Frankland. Infants must be treated individually, for they are individuals, however generic in their behaviour. Nothing can replace the human mammary gland; the next best thing to it is the human mind intelligently trained. We take it, however, that Dr. Hastings Young is not suggesting that the overloaded curriculum of the student should have added to it the chemistry of infant feeding as a compulsory subject. The lesson of his book is that in clinical lectures dietetics should be given a regular place, and that examiners should take the subject into consideration.

Practical Physiological Chemistry. By PHILIP B. HAWK, M.S., Ph.D. Third edition, revised and enlarged. London: J. and A. Churchill. Pp. 440. Price 16*s.* net.—This is an eminently practical book which should be of great service to the laboratory student. It has run rapidly into three editions, the first having been issued in 1907 the

second in 1909, and the third recently. The favourable reception which has been accorded to the book speaks well for it. The pages show care in regard to revision and in the choice of trustworthy analytical methods. There are two full-page plates of absorption spectra in colours, four additional full-page colour plates illustrating microscopical preparations, and 127 figures, of which 12 are in colours. The plan of the book assumes that the student possesses some knowledge of chemistry and physiology, as otherwise he would find the opening chapter on enzymes difficult to follow, but it is just the chapter for the student about to attack practical considerations, and an account of enzymes usefully precedes the sections on carbohydrates, salivary digestion, and the decomposition, synthesis, classification, and properties of the protein. Gastric digestion follows in proper sequence, then discussion of the fats, pancreatic digestion, bile, and putrefaction products. Excellent practical chapters on fæces, blood, milk, and urine find their places afterwards in logical order. Footnotes throughout the pages serve the purpose of recording most recent experimental work, and of giving further analytical details, as, for example, the preparation of test reagents and hints on laboratory procedure. The book is an excellent presentation of the subject, is up-to-date, and clear in its directions.

Makers of Mischief. By STANLEY PORTAL HYATT. London: T. Werner Laurie. 1911. Pp. 275. Price 6*s.*—Mr. Hyatt, whose vigorous style, well-drawn characters, and power of depicting a scene in a few words please readers who may not always be at one with him in all his opinions, has given us another novel with South Africa for its setting. The "makers of mischief" are certain political agents of a foreign power whose machinations, in order to get concessions of land, stir up strife between white men and the natives. The story, which opens in the year 1888, takes the reader back to the time when a large part of what is now British South Africa was entirely in the hands of savages, and it tells how an experienced English hunter, together with his less experienced cousin, cross the almost waterless Kalahari desert in search of a rumoured rare animal, while another young Englishman is left to guard the camp and its treasures during the absence of the hunting party. The stirring adventures of the travellers across the desert, the surprises which awaited them at the end of their journey, the attack on the camp, and the subsequent happenings in the land of the Matabele, will be followed with sustained interest from the first to the last chapter.

MEDICINE AND THE LAW.

An Action arising out of the Sale of a Medical Practice.

IN an action recently tried by Mr. Justice Scrutton sitting without a jury, points of law were raised of some interest, in addition to the questions of fact usually at issue, where the value of a medical practice is questioned after a sale has taken place. The plaintiff, the widow of a medical man, claimed for the balance of the price agreed to be paid by the defendant to her for her introduction to the practice of her late husband and to patients whom he had attended, for board and lodging and for furniture, and also damages for the breach of an agreement to take a lease of the house in which the practice was carried on and which was the plaintiff's property. The defendant denied the items of the claim, and counterclaimed for damages for misrepresentation as to the character of the practice, for £60 as fees for medical attendance on the plaintiff's family, and for breach of the agreement to introduce him to patients. The plaintiff, in her reply as to the sum of £60 for attendance, pleaded an immemorial custom of the medical profession to attend members of the profession, their wives and families without charging for so doing, and in the alternative alleged that the charges were excessive. The legal points referred to arose out of the fact that the affairs of the deceased were in the hands of the Official Receiver, and that the widow had not taken out letters of administration, the defendant's case being that if any money was due from him in respect of the value of the practice it must be for the sale of the goodwill, the price of which should go to the estate. Considerable argument took place with regard to the question of goodwill in the case of a medical practice as distinct from a trade or business, and a number of cases bearing upon the subject were cited. The defendant did not deny that he had had board and lodging in the plaintiff's house and that she had introduced him to some patients. He had also written a letter to the plaintiff thanking her for what she had done, and had expressed his "profound gratitude and respect." Evidence was given as to the customs in connexion with the sales of practices, and with regard to the medical attendance of the defendant upon the plaintiff's children and upon a servant. There had been serious illness among the children. Upon the question whether the payment for the practice was due to the plaintiff or to the estate, it was argued on behalf of the plaintiff that the agreement was personal between her and the defendant. She occupied the house, which was her own, and she was able to introduce him. Mr. Justice Scrutton, in giving judgment, reviewed the facts as outlined above, and upon the question of goodwill said that in the case of a medical man a successor was ready to pay a sum calculated upon the past profits of his practice, and that this appeared to be paid in respect, firstly, of an unreasonable propensity in human beings to continue going to the old house, which gave that house a certain value, and secondly, in respect of the fact that if people were told that the incomer was the successor of the previous occupant of the practice, who had treated them, they would be induced to employ that successor. He considered that the plaintiff had sold the right to carry on the practice in the old house, which, in fact, was hers, and also that she had in the second place sold the right to say "I am Dr. ——'s successor." The first right was personal to the plaintiff and had nothing to do with the estate; as to the second he had some difficulty in deciding, but though inclined to think that it belonged to the estate it had been included with the first in one contract by the widow, and he held that she could sue on that contract, although the estate might afterwards claim its share from her. He therefore decided in favour of the plaintiff as to the claim for the balance of the purchase price. As to the introductions, he referred to the letter mentioned above and refused to find that there had been a breach of contract or misrepresentation. With regard to board and lodging he held that the sum of £2 per week was a fair charge. As to the question of charges for medical attendance on the plaintiff's children and servant, he found that there was not a binding custom but a very general practice not to charge the widow and children of a deceased medical man for attendance shortly after his death. In ordinary circumstances, where medical advice was sought and nothing was said as to payment, there was an implied contract to pay ordinary charges. In a case where a practice of not charging existed, if a medical practitioner intended to charge he should say so, and then the patient would have the opportunity of seeking another medical attendant. In the case before him the defendant would have realised if this had been done that the plaintiff would have been recommending him to her late husband's patients, and at the same time calling in another medical man to treat her own family, which would obviously have been prejudicial to himself. With regard to the servant, he was of the opinion that the defendant attended her without intending to make her mistress liable, and that he must seek payment from the servant herself. He gave judgment for the plaintiff on the claim for a sum to be calculated upon his findings, and also for the plaintiff upon the counterclaim.

A full report of the legal argument will be found in the *Times*, to which we have been indebted.

MANCHESTER SURGICAL AID SOCIETY.—According to the annual report of this society 559 applications were dealt with last year, as against 483 in 1910. The society provides necessary surgical appliances for applicants too poor to buy them. As in the case of most hospital and allied societies the year closed with an overdraft on the bank.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TUESDAY, NOV. 28TH.

Penal Cases.

THE Council took up the consideration of penal cases.

The first case to be decided was that (adjourned from May 24th, 1911), of Arthur William Wilson, registered as of 102, Tufnell Park-road, N., M.B., Mast. Surg. 1887, Univ. Edin., who had been summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

That you have knowingly and wilfully on various occasions assisted one Arthur Jacobs, of Jacobs and Clark, 156, High-street, Camden Town, a person not registered as a dentist, in carrying on practice as a dentist by administering anæsthetics on his behalf to persons coming to him for treatment. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

The complainants were the Society of British Dentists.

At the conclusion of the proceedings on May 24th, 1911, the following decision of the Council was announced by the President:—

Arthur William Wilson: I have to inform you that the facts alleged against you in the notice of inquiry have been proved to the satisfaction of the Council. The Council has not proceeded to pronounce judgment on the facts proved; but has postponed it to the next session of the Council, when you will be required to attend and to produce evidence as to your good conduct in the interval from persons in the neighbourhood familiar with your practice.

Mr. Wilson appeared in person and was accompanied by his solicitor, Mr. Lees.

Mr. LEES submitted to the Council a statutory declaration from Mr. Wilson to the effect that the latter had not, since the last session of the Council, assisted any unregistered person in any way, and that he had faithfully observed in the letter and spirit the undertaking that he gave to the Council.

Communications were read from medical men and other persons of position testifying to the good conduct of Mr. Wilson.

The PRESIDENT, in announcing the decision of the Council, said: Mr. Arthur William Wilson, I have to inform you that the Council, having taken account of the evidence you have produced and the assurances you have given, have not seen fit to direct the Registrar to erase from the Medical Register the name of Arthur William Wilson.

The next cases to be considered were those (adjourned from May 26th) of James Robertson Wallace, now registered as of 68, Jermyn-street, London, S.W., M.B., Mast. Surg. 1885, Univ. Edin., and Charles Edward Trimble, now registered as of 68, Bute-street, Treherbert, Glamorgan, Lic. R. Coll. Phys. Edin. 1898, Lic. R. Coll. Surg. 1898, Lic. Fac. Phys. Surg. Glasg. 1898, who had severally been summoned to appear before the Council on the following charge, as formulated by the Council's solicitor:—

That you have associated yourself in your professional capacity with an institution, termed the Sandow Curative Institute, which systematically advertises for the purpose of procuring patients who are to receive, either by correspondence or by attendance at the said institute, treatment for disease under the personal direction of Eugen Sandow, who is not a registered medical practitioner, and that you have approved of and acquiesced in such advertising. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

The complainants were the British Medical Association.

At the conclusion of the proceedings on May 26th, 1911, the following decision of the Council was announced by the President:—

Mr. James Robertson Wallace: I have to inform you that the facts alleged against you in the notice of inquiry have been proved to the satisfaction of the Council, but that the Council, in order to give you an opportunity to reconsider your position, has postponed judgment in your case till the next session, when you will be required to be present and to produce evidence as to your conduct in the interval.

Mr. Charles Edward Trimble: I have to inform you that the facts alleged against you in the notice of inquiry have been proved to the satisfaction of the Council, but that the Council, in order to give you an opportunity to reconsider your position, has postponed judgment in your case till the next session, when you will be required to be present and to produce evidence as to your conduct in the interval.

The case of Mr. Trimble was first considered. He appeared in person and submitted a statutory declaration to the effect that he had had no connexion whatever with the Sandow Institute since he appeared before the General Medical Council in May last. He had given up his post there in April last, and had had absolutely nothing to do with the institute since. A testimonial as to character from a medical practitioner was read.

The PRESIDENT announced the decision of the Council as follows: Mr. Charles Edward Trimble, I have to inform you that having regard to the evidence you have produced and to your conduct since the last session of the Council, the Council does not see fit to direct the Registrar to erase your name from the Medical Register.

The Council then considered the case of Mr. James Robertson Wallace. Mr. Wallace appeared in person and was represented by Lord Robert Cecil, K.C., and Mr. A. Neilson, instructed by Mr. G. Lewis, solicitor.

The complainants were represented by Mr. Smith Whitaker.

Lord ROBERT CECIL at the outset took objection to a statutory declaration lodged by the complainants on the ground that it was dated Nov. 23rd. He submitted that it did not comply with the Standing Orders of the Council, which laid down that seven days' notice of any further facts and evidence should be given to the accused practitioner.

Mr. SMITH WHITAKER said that the complainants submitted this document in reply to the declaration of Mr. Wallace and to the communication of the solicitor to the Council asking whether it was the complainants' desire to submit any evidence to the Council.

The LEGAL ASSESSOR (Mr. BODKIN) ruled that the statutory declaration in question did not comply with the Standing Orders, and that any evidence which it was proposed to tender in connexion with it could not be properly received or considered by the Council. The document had been sent to members of the Council, but as they were acting in a completely judicial capacity any statements or facts in it which had been read by members of the Council would not operate in any way upon their minds, and would be completely disregarded by them in considering the evidence which would be adduced to the Council.

Lord ROBERT CECIL said that his client had sought but had been unable to ascertain from the Council what they desired him to do. He was in a very difficult position. He had to consider exactly what he had to do and what was the objection of the Council to his conduct in the past. Counsel argued that what his client had to avoid was (1) association with an institution which undertook the treatment of disease and which systematically advertised for patients, and (2) the aiding and abetting an unregistered person in the treatment of disease. If he avoided these things he was not guilty. The Sandow Curative Institute now neither systematically nor in any way advertised for the purpose of procuring patients who were to receive treatment for disease under the direction of Mr. Eugen Sandow. Lord Robert Cecil proceeded to read a declaration made by Mr. Wallace, in which he stated that upon this alteration being made in the Sandow Institute he resumed the duties which he had suspended. Since that date he had superintended, advised, and accepted responsibility for the treatment of persons who came to the institute for the course of exercises. No advertisements were now issued. The treatment at the institute was therefore now absolutely under the control of Mr. Wallace, and was given by him as a responsible medical man in pursuance of his judgment as to what was required. He accepted full responsibility for everything that was done under his direction. All the treatment was done under the direct superintendence of a medical man and without advertising. Mr. Wallace had therefore avoided what it was necessary for him to avoid. Lord Robert Cecil intimated, in conclusion, that he would not call Mr. Wallace as a witness as he had no questions to ask him, but he tendered him for cross-examination if required.

After some discussion with the Legal Assessor Mr. Wallace entered the witness-box.

Mr. SMITH WHITAKER: Has there been any change in the practice of the Sandow Institute?

Mr. WALLACE: Yes.

What is it?—I see all the patients and I prescribe the broad lines of treatment on which the exercise is to be given. I take the whole responsibility of the medical treatment of the case.

Does Mr. Sandow see cases now and again?—Now and again.

Does he accept any responsibility?—No, I accept the whole.

Then the whole of the Sandow Institute is carried on under your guidance?—Yes, so far as the medical treatment is concerned.

Mr. SMITH WHITAKER then submitted that although the advertising might be discontinued the profits of the advertising remained. This practitioner had continued in the employment of the institute, his association with which was condemned by the Council.

After deliberation *in camerâ* the PRESIDENT said: Mr. Robertson Wallace, I have to inform you that the Council are not satisfied with the evidence as to your conduct which you produce, and they have accordingly decided to give you a further opportunity of producing more satisfactory evidence regarding your professional conduct. Such evidence, they instruct me to tell you, ought to be testified by medical practitioners or other persons of position who may be acquainted with your practice and conduct in the interval, and for this purpose they are postponing judgment on your case once more until the next session of the Council.

The Council adjourned.

WEDNESDAY, NOV. 29TH.

The Council resumed its sittings at its offices, 299, Oxford-street, W. Sir DONALD MACALISTER, the President, was in the chair.

Penal Cases.

The Council dealt with charges against medical practitioners.

The first case considered was that of William Dutton Akers, registered as of 67, Sackville-road, Hove, Lic. Soc. Apoth. Lond. 1892, Mem. R. Coll. Surg. Eng. 1898, Lic. R. Coll. Phys. Lond. 1898, who had been summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

That you abused your position as a medical man by committing adultery with a Mrs. Geddes, with whom you stood in professional relationship, of which adultery you were found guilty by the decree of the Probate, Divorce and Admiralty Division (Divorce) of the High Court of Justice, dated Dec. 16th, 1910, in the case of Geddes *v.* Geddes and Akers, in which you were the co-respondent, which decree was made absolute on June 26th, 1911. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

There was no complainant in this case, nor did Mr. Akers attend in answer to his notice.

After certain evidence had been submitted the PRESIDENT announced the judgment of the Council as follows: I have to announce that the Council have judged William Dutton Akers to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase from the Medical Register the name of William Dutton Akers.

The next case to be considered was that of James Williamson Skelley, registered as of Blaenrhondda, Treherbert, Glamorgan, Lic. R. Coll. Phys. Edin. 1905, Lic. R Coll. Surg. Edin. 1905, Lic. Fac. Phys. Surg. Glasg. 1905, who had been summoned to appear before the Council on the following charge, as formulated by the Council's solicitor:—

That you abused your position as a medical man by committing adultery with a Mrs. Unwin, whom you had been attending professionally, of which adultery you were found guilty by the decree of the Probate, Divorce, and Admiralty Division (Divorce) of the High Court of Justice, dated June 14th, 1911, in the case of Unwin *v.* Unwin and Skelley, in which you were the co-respondent. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

The complainant was Mr. Clyde Longman Hayes, a registered medical practitioner.

Mr. Skelley attended, accompanied by Mr. Wing, solicitor. The complainant was represented by Mr. Neal, solicitor.

Evidence was submitted to the Council in relation to the charge. This included accounts for professional work.

Mr. SKELLEY gave evidence on his own behalf and stated that he had become acquainted with Mrs. Unwin prior to her marriage and also before he had attended her professionally.

The PRESIDENT announced the judgment of the Council as follows: James Williamson Skelley, the Council have judged you to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase from the Medical Register the name of James Williamson Skelley.

The Council then considered the case of George William Hammond. The Dental Committee reported:—

The said George William Hammond was registered in the Dentists Register on December 31st, 1878, as "in practice before July 22nd, 1878," and his address in the Register for the current year is Dental House Ripon.

The Committee find that the following facts were established by the evidence: That on March 22nd, 1911, the said George William Hammond was convicted at Ripon of the following offence, of attempting to steal certain goods from the Church Lads' Brigade Club Room in Allhallowgate, and that he was sentenced to three months' imprisonment with hard labour.

Mr. Hammond sent a letter stating that he would not be able to be present.

The PRESIDENT announced the judgment of the Council as follows: I have to announce that the Council, having considered the facts found in the report of the Dental Committee, does not direct the Registrar to remove from the Dentists Register the name of Mr. George William Hammond.

The next case to be considered was that of John Edwards, registered as of 1, Chadwell Heath-lane, Chadwell, Essex, Lic. Soc. Apoth. Lond. 1893, who had been summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

That you were on Sept. 5th, 1911, convicted at the Central Criminal Court on your own confession of the following misdemeanour—namely, of having unlawfully and knowingly signed a false declaration of your personal knowledge and belief and thereby enabled one Reuben George Rittman to obtain a passport for travel in a foreign country, for which offence you were fined £25.

Mr. Edwards appeared, and was accompanied by Mr. Forrest Fulton, his counsel.

Mr. FORREST FULTON, in addressing the Council on behalf of his client, said that on behalf of Mr. Edwards he desired to express deep regret for what had happened. What Mr. Edwards had done was rather an act of negligence committed in a hasty moment than a deliberate act. What he did was to oblige a man whom he believed to be known to the medical man for whom he was acting. Mr. Edwards was acting in Wandsworth for a medical man who was in bad health, and he was dependent on others for his knowledge of the patients. One night, when the surgery was particularly full, a man entered and asked Mr. Edwards to sign a paper for him. Mr. Edwards was led to believe that this man was the son of some patient of the medical man for whom he was acting. He appended his signature and the man went away. The document in question had not been in use for any lengthened period. It was only when the summons was served upon him that Mr. Edwards remembered vaguely what had occurred.

Mr. EDWARDS went into the witness-box and expressed his great regret.

The PRESIDENT announced the judgment of the Council as follows: Mr. Edwards, I have to inform you that the Council have found your conviction proved; that the Council takes a grave view of the giving of certificates of an irregular character, but that, having taken into consideration all the facts of your case and the assurances that you have given, the Council has not seen fit to direct the Registrar to erase your name from the Medical Register.

The Council adjourned.

THURSDAY, NOV. 30TH.

The Council resumed its sittings at its offices, 299, Oxford-street, W. Sir DONALD MACALISTER, the President, was in the chair.

The Case of Major Fink.

The Council considered the case of George Herbert Fink, registered as of Queen's Gate Chambers, 52A, Cromwell-road, South Kensington, London, S.W., Lic. Soc. Apoth. Lond. 1882, Mem. R. Coll. Surg. Eng. 1883, who had been summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

That you were on Nov. 10th, 1911, convicted at the Central Criminal Court of the following felony—namely, of forging a banker's cheque for £11,000 3*s.* 10*d.* with intent to defraud, and found guilty but insane so as not to be responsible according to law, and thereupon ordered to be kept in custody during His Majesty's pleasure.

Major Fink was not present, nor was he represented.

Mr. HARPER (one of the solicitors to the Council) said that the case was a very sad one. In 1886 it appeared that Major Fink joined the Indian Medical Service and was attached to the Bengal Lancers, and until 1900 he was in service in India and he had worked very hard in malarial and

insanitary districts. He served with distinction on the North-west frontier, for which he received the medal and clasp. In 1900 he was invalided home on furlough and applied for an extension of leave, which was refused. He at once sent in his papers and retired on a pension of less than £300 a year. If he had remained another three years in the service he would have been entitled to a much larger one as a Lieutenant-Colonel, and his wife would also have been entitled to a pension on his death. The precipitate action of sending in those papers rather indicated the state of his mind then. Since then he had been very strange and eccentric, and had an ungovernable temper and committed acts of violence at home. About 1907 he opened a deposit acount with the National Discount Company in the City and placed there £600, which he drew on from time to time, until finally there was only £11 3*s*. 10*d*. standing to his credit, which he wished to draw out. In accordance with their custom the bank gave him a cheque drawn by the National Discount Company to the order of Major Fink upon the Union of London and Smith's Bank for that amount. The next day Major Fink telephoned to the National Discount Company that he had lost the cheque, and it was arranged that he should come to the company the following morning to make arrangements for the issuing of a fresh cheque on the usual indemnity. On the same day the manager of the London branch of the Delhi bank received the cheque altered from £11 3*s*. 10*d*. to £11,000 3*s*. 10*d*., together with a letter requiring cash or cheque for the amount. It was said that the alteration was done cleverly, but not in such a way as to deceive any cashier. They sent the cheque to the National Discount Company, who took the matter up. Major Fink was prosecuted, with the result that he was found to be insane. The family had consulted Dr. Maurice Craig as to the condition of Major Fink. Mr. Harper read a letter from Dr. Maurice Craig, dated Nov. 2nd, 1911, and addressed to the General Medical Council. It was in the following terms:—

As you state, I gave evidence at the Old Bailey regarding the mental state of Major Fink. When I saw him I considered that he was a person of unsound mind, and that he had been for some long period. I further stated that I was perfectly prepared to certify him as such. In fact, if what he did can be called a forgery, it was done during a state of mental confusion. As I daresay you know, what he had done was not likely to deceive anybody. Although he had altered the face of the cheque, he had also written other instructions on the back of it, which showed clearly that he was unsound mentally at the time. He is suffering from delusions of persecutions, his illness having been brought about by active service in India, together with dysentery, malaria, &c. As regards the outlook it is impossible for me to say that he will not recover, as these exhaustion cases often clear up under enforced rest, but I did not form a hopeful view of his case.

It was obvious, Mr. Harper added, that Major Fink had no criminal intent. However, after the finding at the Old Bailey it was necessary that the case should be brought before the Council, but it was not necessary for the Council to pass upon him the stigma of finding that he had committed an act implying infamous conduct.

The PRESIDENT announced the decision of the Council as follows: The Council having regard to all the circumstances of the case does not see fit to direct the Registrar to erase from the Medical Register the name of Mr. George Herbert Fink.

Warning Notice as to Professional Conduct.

The Council then sat *in camerâ* to consider the advisability of issuing a warning notice directing the attention of medical men to the resolutions of the Council regarding "infamous conduct in a professional respect." Afterwards it was announced that the Council had agreed to the following notice:—

GENERAL MEDICAL COUNCIL.

Preliminary.—The General Medical Council consider that in the interests of the medical profession it is advisable to bring to the notice of its members certain resolutions which have from time to time been adopted as expressing the views of the Council upon certain forms of professional misconduct which have been or may be dealt with as amounting to "infamous conduct in a professional respect" within the meaning of Section 29 of the Medical Act of 1858. The Council, however, wish it to be distinctly understood that these resolutions are not exhaustive of the forms of professional misconduct which may be dealt with by the General Medical Council under their disciplinary powers, and that the Council are not in any way precluded from considering and dealing with any form of professional misconduct outside the scope or precise language of the resolutions.

AS TO THE SIGNING OF CERTIFICATES.

Resolution adopted by the General Medical Council on Nov. 30th, 1911:—

Whereas registered medical practitioners are in certain cases bound by law to give, or may be from time to time called upon or requested to give, certificates signed by them in their professional capacity, for subsequent use either in courts of justice or for administrative purposes, And whereas such certificates include, amongst others—

Certificates.—(*a*) Under any statute relating to births, deaths, or disposal of the dead; (*b*) under the Lunacy Acts; (*c*) under the Vaccination Acts; (*d*) under the Factory Acts; (*e*) in relation to children or to excusing school attendance; (*f*) in connexion with sick benefit, insurance, and friendly societies; (*g*) in connexion with workmen's compensation; (*h*) in connexion with naval or merchant shipping; (*i*) for procuring the issue of Foreign Office passports; (*j*) for excusing attendance in courts of justice, in public services, in public offices, or at ordinary employments.

And whereas it has been made to appear from time to time that some registered medical practitioners have given and signed untrue, misleading, or improper certificates of the above-specified or other descriptions,

Now the General Medical Council hereby give notice that any registered medical practitioner who shall be shown to have given any untrue, misleading, or improper certificate, *whether relating to the several matters above specified or otherwise*, is liable to be adjudged by them to be guilty of "infamous conduct in a professional respect" and to have his name erased from the Medical Register under Section 29 of the Medical Act, 1858.

The Council adjourned.

FRIDAY, DEC. 1ST.

The Council resumed its sittings at its offices, 299, Oxford-street, W. Sir DONALD MACALISTER, the President, was again in the chair.

Apothecaries' Hall, Dublin.

The report as to the final examinations held by the Apothecaries' Hall, Dublin, in July and October, 1911, was considered.

Sir DAVID MCVAIL said that at the last two or three examinations of the Apothecaries' Hall, Dublin, no paper in midwifery had been set. Papers had been set in medicine and surgery. Formerly a paper in midwifery had been set, but it had been dropped. The only examination that was held on this subject now was a clinical one, and one of the examiners said that that was an oral examination as well. It was for the Council to consider whether it was desirable that in one of the three great subjects a written paper should be dropped. The Examination Committee was of opinion that a paper on the subject of midwifery should always form part of the examination. He moved that the report of the Examination Committee should be adopted by the Council and communicated to the Apothecaries' Hall, Dublin.

This motion was agreed to.

Teaching Institutions and the Preliminary Sciences.

A report was received from the Students' Registration Committee on exceptional cases and on the approval of certain recognised teaching institutions. The latter part of the report set forth that applications had been received for the approval by the Council of the following institutions in regard to the preliminary sciences: Cheltenham College; Dulwich College; Epsom College; Eastbourne College; Felsted School; Harrow School; Hymer's College, Hull; King Edward's School, Stourbridge; Malvern College; Repton School; Trent College, Long Eaton; Whitgift Grammar School, Croydon; and the Technical College, Darlington; all of which were recognised by the English Conjoint Board.

It was resolved by the committee—

1. That, satisfactory evidence as to visitation having been received from the chairman, Cheltenham College, Dulwich College, Epsom College, Eastbourne College, Felsted School, Harrow School, King Edward's School (Stourbridge), Malvern College, Repton School, Trent College, and Whitgift Grammar School be added to the list of recognised institutions approved by the Council.
2. That the Technical College, Darlington (day classes), be added to the list of recognised institutions approved by the Council.
3. That the Committee proposes to draw up a form of application for approval by institutions for regular use.

Dr. NORMAN MOORE, in moving that the Council should approve of the resolution of the committee, drew special attention to the third clause in it. It would be of advantage to have a common form of application which would be filled up by every institution which applied for approval.

Dr. MACKAY seconded.

Dr. CATON asked whether the adoption of the resolution by the Council would place the schools mentioned in the same position as a department teaching the particular subjects in a university or medical school, or was the instruction given in these schools to be preliminary to the study of the same subjects and to be followed up in medical schools.

Dr. NORMAN MOORE said that the student who had attended the courses on chemistry and physics or biology in one of these approved schools, and had passed the examination of the qualifying bodies in these subjects, would not be required to pursue a further course in them unless the particular licensing body, such as the University of London, required

further knowledge. Of course the student would have to comply with the requirements of the particular qualifying body whose curriculum he was pursuing.

Sir HENRY MORRIS intimated that in the next session of the Council he would bring forward a suggestion in the form of a motion that the Council should recommend to all the licensing bodies, whether universities or medical schools, that the study which was taken at these approved institutions should not be allowed—even if it extended over two or three years—to count as more than six months of the medical curriculum. He was prepared to move that if the study were taken in these approved institutions, and if the examination were not passed until three months after the student had entered the medical school, the medical curriculum should be four years and nine months. If the examination were not passed until six months after entering a medical school, he would suggest that no part of the time spent on these studies at any recognised *non-medical* institution, be it either technical science school or college, or polytechnic or secondary school, should be allowed to count as any part of the five years' curriculum. The non-approval by the Council of these institutions had retarded the growth of the public and secondary schools in this country in the direction of being places in which instruction in science was given as well as general culture. He wanted to encourage the secondary schools to become something like the *Real-Gymnasia* in Germany. The attitude of the Council hitherto had been to retard such development in the secondary schools in this country. He also added that in any revision of the subjects of the curriculum it would be a good thing to make it necessary to pass an examination in elementary science as well as in general education before entrance at a medical school, and to add to anatomy and physiology of the first two or two and a half years some amount of chemistry and physics in their application to physiology and pathology, for which there would be ample time.

Sir CLIFFORD ALLBUTT remarked that he would be very sorry if students came up to his own University, and having passed the elements of chemistry and physics, would lay these subjects aside without making further advances in them.

Sir C. NIXON thought that there ought to be strict uniformity in connexion with this matter. In the Universities it was laid down that the medical curriculum should extend over five years from the date of registration. So far as he knew, with few exceptions, the Universities had been loyal to the recommendations of the Council. If now recognition was given to the lectures in physics, chemistry, and biology in secondary schools, and this instruction counted for six months out of the first year of medical study, why should Universities be required to have the whole five years? If the recommendations of the Council were followed, it must exact from medical students the full term of the curriculum. He saw the possibility that the universities might claim for their students the same privileges as the Conjoint Board claimed for its students.

The PRESIDENT observed that the Council had not laid down under what conditions the study thus commenced would be reckoned towards the five years' curriculum. That would be dealt with in June.

Dr. NORMAN MOORE: No part of the five years' study can count until the registration examination has been passed.

Dr. MACKAY said that at the last meeting of the Council it granted recognition to secondary schools under defined conditions. These conditions had been fulfilled by the schools, the names of which were now before the Council. What the committee had done was to put these schools as regarded the subjects in question in the same position as medical schools and polytechnics. There were no regulations different from those of medical schools. What the Council had now to do was to say whether it approved of the schools which the committee had placed before it. These schools were amongst the best in the land.

Sir JOHN MOORE: Who are the visitors under this recommendation?

Dr. NORMAN MOORE: What the Council requires is visitation by a licensing body. The licensing body is responsible for the visitation.

Sir THOMAS FRASER: What is the evidence which the committee had before it as to the fitness of the schools?

Dr. NORMAN MOORE: This Council has no power, so far as I know, of visiting these schools. It certainly had never exercised it. All the medical schools of this country, and all the hospitals in which medical students received their professional instruction, had to be recognised by the qualifying bodies. The Council accepted that. It did not go and visit each. From these schools for which approval was now sought no application could be received unless the qualifying body stated after visitation and inquiry that it was satisfied.

Dr. CATON said that he was sorry that the Council had not been able to consider the memorials from the universities. He wished that it was possible to delay recognition until the matter had been fully discussed.

Dr. NORMAN MOORE: It has been discussed for ten years.

Dr. CATON: It was discussed very briefly and hurriedly.

The PRESIDENT: Communications from three universities have been received which, I think, ought to be referred to the Examination Committee.

Dr. MACKAY said that the Council was bound to consider applications in view of its own resolution.

The Council then agreed to the motion to approve of the resolutions of the Committee.

Medical Certificates and Diplomas in India.

The Students' Registration Committee stated in its report that it had had before it an application from the All-India Sub-assistant Surgeons' Association. That association had passed a resolution in the following terms:—

That a representation be sent to the Medical Council of the United Kingdom for requesting that body to recognise the course of the study of the sub-assistant surgeons in the medical schools of the United Kingdom, in view of the fact that the sub-assistant surgeons undergo a regular four years' training in recognised Government medical schools, and that the Government have admitted their claims to the Medical Registration Act.

The Students' Registration Committee resolved:—

That this application be recorded, but that the committee, in view of the fact that legislation is contemplated, defer further consideration of it for the present.

Sir DAVID MCVAIL moved:—

That the Examination Committee, together with the chairman of the Education Committee and the chairman of the Students' Registration Committee, be requested to obtain full information regarding the conditions under which medical certificates or diplomas are granted in India, and to what extent, if any, *pro tanto* recognition of curriculum and examination should be given by licensing bodies in Great Britain and Ireland, and to report to the Council.

He said that the committee had had a great deal of trouble over this matter. Certain information was desired which only the Government of India could supply. The India Office had written to India to secure it for the committee.

Dr. MACKAY seconded.

The motion was agreed to.

Registration of Medical Students.

Dr. MACKAY submitted a report of the Education Committee upon a resolution submitted to it as to the regulations in regard to the registration of medical and dental students. That resolution directed the committee to report to the Council what alterations in the Regulations (10, 11, and 12) for the Registration of Medical Students were necessary to bring them into conformity with the facts and with the powers of the Council. The Committee recommended—

I. That the following should be substituted for Clauses 10, 11, and 12 above quoted—

It is recommended by the Council—

(10) That every medical student should be registered in the manner hereinafter prescribed.

(11) That no medical student should be registered until he has attained the age of 16 years, has passed a preliminary examination recognised by the General Medical Council, and has produced evidence that he has commenced medical study at a university, or school of medicine, or at a teaching institution recognised by one of the licensing bodies and approved by the Council.

(12) The commencement of the course of professional study recognised by any of the licensing bodies should not be reckoned as dating earlier than 15 days before the date of registration.

II. That the changes recommended in this Report will, in the opinion of the Committee, necessitate a recasting of the Resolutions passed by the Council regarding professional education.

Dr. MACKAY, in moving that the recommendations framed by the committee should be adopted by the Council, said that in Regulation 11 the committee had substituted the words "teaching institution" for "scientific institution," in view of the fact that the Council had recognised certain secondary schools. The other changes were that the imperative "shall" had been replaced by the permissive "should."

Mr. HODSDON seconded.

Dr. ADYE-CURRAN thought that the substitution of

"should" for "shall" was a recognition of the fact that the Council had exceeded the scope of its authority.

The PRESIDENT, in putting the motion, said that he did so on the clear understanding that if it was carried it would be remitted to the Education Committee to draw up a fresh statement of the regulations embodying the changes.

The motion was agreed to.

Preliminary Examination of the Royal Colleges in Ireland.

Sir ARTHUR CHANCE had given notice of the following motion:—

That any "Requirements or Regulations" of this Council regarding the standard in General Education to be observed in Preliminary Examinations which are compulsory on any Irish Examining Body, in the sense that their observance is regarded by the Council as essential for the continued recognition by the Council of the Preliminary Examination of such Irish Examining Body, shall apply equally to all the Irish Preliminary Examinations in general knowledge recognised by this Council.

He said that he would move his motion in an altered form. It would be as follows:—

That as far as concerns the preliminary examination in general education, the Conjoint Board of the Royal Colleges in Ireland shall be regarded by this Council as if the Conjoint Board were a university examining body.

Sir Arthur Chance went on to say that the Irish Conjoint Board only wanted to be treated in the same way as its competitors, and he did not care what the form of words adopted was if this result was attained. The Conjoint Board was, owing to the peculiar circumstances obtaining in Ireland, forced to hold this preliminary examination. It had appointed a number of gentlemen of the very highest university standing to conduct it, and had deprived itself of any power to interfere with the discretion of these gentlemen. They therefore virtually, although not nominally, formed a university examining board. The Colleges were anxious to keep up a high standard of education. The Universities were free from certain matters which were laid down by the Education Committee, and the Colleges ought to be placed in the same position as these other bodies.

Sir JOHN MOORE seconded.

Dr. LITTLE remarked that the Council had no right to put this examination on the same footing as that of any university. He would, however, be prepared to support a motion such as Sir Arthur Chance had originally placed on the paper.

Sir CHARLES BALL said that he could support the motion originally placed on the paper. The examination was known to be a good one.

Dr. MACKAY said that the Council was being asked to do something which it possibly could not do. He would point out that a university was an integral part in the educational system of the country.

Sir C. NIXON said that the examination in question was admitted to be a good one, and the examining body seemed to be perfectly free from interference by the Conjoint Board. But the examination had nothing to do with the universities, and the universities would resent any proposal that there should be any assimilation of their examinations with the examination of the Conjoint Board.

The PRESIDENT remarked that all that was desired by the Irish Colleges was the admission that they had established an independent Educational Board, that that Board had established a suitable standard of examination, and that that was recognised on its merits. The Council did not need to raise the question of equivalent examinations so long as the particular examination was sufficient.

Sir ARTHUR CHANCE after further debate withdrew his motion.

Regulations for the Diploma in Public Health.

The Public Health Committee submitted a final report in regard to the proposed revision of the regulations for the Diploma in Public Health, together with the comments of the qualifying bodies thereon. The committee proposed that the resolutions and rules adopted by the General Medical Council for Diplomas in Public Health should be as follows:—

I.—The Council, having regard to the terms of Section 18 of the Local Government Act (1888) and of Section 54 of the Local Government (Scotland) Act (1889), and observing that under those sections special privilege is to be accorded to the holders of the diplomas granted under Section 21 of the Medical Act (1886), and therein described as Diplomas in Sanitary Science, Public Health, or State Medicine, thinks it essential to declare, with regard to its own future action under Section 21 of the Medical Act (1886), that it will not consider diplomas to "deserve recognition in the Medical Register" unless they have been granted under such conditions of education and examination as to ensure (in the judgment of the Council) the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health; and the Council, in forming its judgment on such conditions of education and examination, will expect the following rules to have been observed:—

Rule 1. The curriculum for a Diploma in Sanitary Science, Public Health, or State Medicine shall extend over a period of not less than nine calendar months.

Rule 2. Every candidate for a Diploma in Sanitary Science, Public Health or State Medicine shall have produced satisfactory evidence that, after obtaining a registrable qualification, which should be registered before admission to examination for the diploma, he has received practical instruction in a laboratory or laboratories, British or foreign, approved by the licensing body granting the diploma in which chemistry, bacteriology, and the pathology of the diseases of animals transmissible to man are taught. The laboratory instruction shall cover a period of not less than four calendar months, and the candidate shall produce evidence that he has worked in the laboratory for at least 240 hours, of which not more than one-half shall be devoted to practical chemistry. The laboratory course should be so arranged as to lay special stress on practical work which bears most directly on the duties of a medical officer of health.

Rule 3. Every candidate shall have produced satisfactory evidence that, after obtaining a registrable qualification, he has during six months been diligently engaged in acquiring a practical knowledge of the duties, routine and special, of public health administration, under the personal supervision of (*a*) in England and Wales, the medical officer of health of a county or of a single or combined sanitary district having a population of not less than 50,000, or a medical officer of health devoting his whole time to public health work; or (*b*) in Scotland, a medical officer of health of a county or counties, or of one or more districts having a population of not less than 30,000; or (*c*) in Ireland, a medical superintendent officer of health of a district or districts having a population of not less than 30,000; or (*d*) in the British dominions outside the United Kingdom, a medical officer of health of a sanitary district having a population of not less than 30,000, who himself holds a registrable Diploma in Public Health; or (*e*) a medical officer of health who is also a teacher in the department of public health of a recognised medical school; or (*f*) a sanitary staff officer of the Royal Army Medical Corps having charge of an army corps, district, command, or division, recognised for this purpose by the General Medical Council. (*g*) An assistant medical officer of health of a county or of a single sanitary district having a population of not less than 50,000, provided the medical officer of health of the county or district in question permits the assistant officer to give the necessary instruction and to issue certificates; or (*h*) That he has himself held for a period of not less than three years an appointment as medical officer of health of a sanitary district within the British Dominions, and having a population of not less than 15,000. The certificate for this purpose must except as provided under (*h*) include testimony that the candidate has attended under the supervision of the person certifying on not less than 60 working days. Provided that if the candidate has:—(1) Produced satisfactory evidence that he has attended a course or courses of instruction in sanitary law, vital statistics, epidemiology, school hygiene, and other subjects bearing on public health administration, given by a teacher or teachers in the department of public health of a recognised medical school; or (2) produced evidence that he has been a resident medical officer in a hospital for infectious diseases containing not less than 100 beds, during a period of three months—the period during which he has been engaged in acquiring practical knowledge of his duties under this rule may be reduced to three months, to include an attendance on at least 30 working days.

Rule 4. Every candidate shall have produced evidence that, after obtaining a registrable qualification, he has attended during three months at least twice weekly the practice of a hospital for infectious diseases at which candidate has received instruction in the methods of administration. 1. Methods of administration shall include the methods of dealing with patients at their admission and discharge, as well as in the wards, and the medical superintendence of the hospital generally. 2. In the case of a medical officer of the Royal Army Medical Corps a certificate from a principal medical officer under whom he has served, stating that he has during a period of at least three months been diligently engaged in acquiring a practical knowledge of hospital administration in relation to infectious diseases, may be accepted as evidence under Rule 4.

Rule 5. The examination shall have been conducted by examiners specially qualified; it shall have extended over not less than four days, one of which shall have been devoted to practical work in a laboratory, and one to practical examination in, and reporting on, subjects which fall within the duties of a medical officer of health, including those of a school medical officer.

*** The Rules 2, 3, 4, as to study, shall not apply to medical practitioners registered, or entitled to be registered, on or before Jan. 1st, 1890.

II.—The Council shall, from time to time, appoint an inspector or inspectors of examinations in public health, with special instructions to report to the Council whether the examination of each licensing body does or does not afford evidence, on the part of candidates passing such examination, of a distinctly high proficiency, scientific and practical, in each and all of the branches of study which concern the public health.

List of the districts and commands that have been recognised by the Council under Rule 3 (*f*):—

Aldershot.
Salisbury Plain.
Southern and South-Eastern.
Western.
Dublin and Belfast.
Cork.
Chatham and Woolwich.
Home.
Eastern.
North-Eastern and North-Western.
Scottish.
Gibraltar Command.
Malta Command.

The following Indian Divisions, viz.:—
1st (Peshawar).
2nd (Rawalpindi).
3rd (Lahore).
5th (Mhow).
6th (Poona).
7th (Meerut).
8th (Lucknow).
9th (Secunderabad).
Burma.

Dr. NORMAN WALKER moved "that the resolutions and rules in their amended form be adopted." He thought that the report of the Public Health Committee was an example of the deliberate way in which medical legislation ought to be carried through. The committee had, firstly, presented draft alterations in the regulations to the Council, and the latter had given directions that these should be sent to the various licensing bodies for their criticisms and comments. The committee had considered the replies very carefully, and as the result of its considerations suggested that in Rule 1 nine months should be recognised. Now he came to the question of laboratory work, and here there was a very considerable difference of opinion. The regulations which were at present in force laid down that the candidate should have worked in a laboratory or laboratories. In its inquiries the committee asked whether this meant six calendar months; and it found that the nominal six months had been reduced in practice to five. In very few places was there made any stipulation as to hours. The proposal for a 13 weeks' course with 150 hours of practical work aroused very strong opposition. As a compromise the committee suggested that the period required should be four calendar months. It further specified that during those four calendar months 240 hours should be devoted to practical work in the laboratories. That was a very considerable stiffening of the regulations.

Dr. NEWSHOLME seconded.

Dr. KNOX said that three months was too short a time, as it would result in cramming, but he would not object to four calendar months as a sort of compromise.

Sir HENRY MORRIS stated that the English Royal Colleges had always had a public health syllabus, and it had quite recently been revised so as to bring it up to modern requirements. The report did not agree with the practice of the Colleges in the reduction of the period in Rule 2 from six months to four. The recommendation from their examiners was that there should not be any cast-iron regulation as to the division of time between chemistry and bacteriology. Examiners found candidates who were so well prepared in chemistry and so badly prepared in bacteriology that they should not be compelled to give so much time to chemistry. Candidates might come to take their course with practical knowledge of one branch. He would be prepared to move an amendment to the effect that the proportion of time to be devoted to chemistry and bacteriology should be left to the discretion of the teachers.

Sir JOHN MOORE said that as chairman of the committee he could not accept such an amendment if it were moved. It had been felt very much in the past that too much time had been devoted to chemistry and too little to bacteriology. There was no doubt about the necessity of a thorough knowledge of bacteriology. He thought that it was a very fair arrangement that not more than one-half of the time should be devoted to chemistry.

Sir WILLIAM WHITLA hoped that the rule would not be made too cast iron in character.

Dr. NEWSHOLME considered that the committee might congratulate itself that the report had been received with so much consent. During the nine months under the proposed rules the instruction and practical work were to be made of a more definite character than was the case formerly.

The motion was agreed to.

Report of the Pharmacopœia Committee.

The Pharmacopœia Committee reported to the Council in the following terms:—

From May 21st to Nov. 18th, 1911, the number of copies of the British Pharmacopœia (1898) sold by the publishers was 581. The total number of copies sold in the year beginning Nov. 19th, 1910, was 1114; this is a larger number than any recorded for several years past. Up to the present time 43,574 copies of the Pharmacopœia and 4511 copies of the Indian and Colonial Addendum have been sold. The stock of the Pharmacopœia now in hand numbers 1439 copies; it will probably suffice for the demand during the next 18 months.

The third report of the Committee of Reference in Pharmacy, with a supplement thereto, has been published, and the Pharmacopœia Committee have received a number of criticisms and comments upon its suggestions, of which note will be taken for subsequent use.

The committee have pleasure in intimating that Dr. Tirard, for many years its secretary, and Professor Greenish, secretary of the Committee of Reference in Pharmacy, have accepted appointment as editors of the new issue of the Pharmacopœia, and are now engaged in classifying the materials relating to the revision of the text which have accumulated in the committee's hands. The committee have to acknowledge the courtesy of the Council of the Pharmaceutical Society of Great Britain, who have been good enough to make arrangements which have facilitated Professor Greenish's acceptance of this appointment.

The editors have submitted for the approval of the committee an outline of the steps they propose to take for the preparation of a first draft of the revised text. These will follow the general lines adopted in connexion with the last revision. It will doubtless be necessary, as on previous occasions, to obtain expert assistance on technical questions from small Committees of Reference in Chemistry and in Botany. The appointment of such committees has been authorised by the committee.

The report was approved of.

Inspection of Qualifying Examinations in Dentistry.

A report was received from the Dental Education and Examination Committee on the inspection of the qualifying examinations in dentistry held during the year 1911. The report concluded thus:—

In reviewing the whole series of inspected examinations their general uniformity and adequacy is striking, and, except in matters of detail, little appears to require amendment. The chief point where differences of practice exist is in the final conference of examiners and in the extent to which the marks originally given are liable to subsequent modification. At the Royal College of Surgeons of Ireland alone there is absolutely no revision of marks once given. At the Royal College of Surgeons of England there is such a revision possible, but it is limited to leniency extended to such as have very nearly attained to a pass mark, whereas in the other bodies it appears, judging from the inspector's reports, to be exercised far more freely, and indeed in some cases the report reads as though the revision were extended in an undesirable degree.

It must be remembered that the mark originally given has had the concurrence of two examiners with the candidate or his paper before them, and was the expression of their deliberate judgment upon his merits. The committee are of opinion that it is not desirable to have a cast-iron rule that under no circumstances can a mark be increased, which might occasionally press hardly upon a candidate who has almost reached the required limit, but that any extension of the practise of revising marks beyond this point must tend to a lowering of the standard.

Your committee are of opinion that the clinical part of the examination in dental surgery is of great importance and should be extended so far as is practicable. And in this connexion it may be mentioned that the inspector desires to add to his report his opinion that in marking this section of the examination credit should be given to candidates for gentleness and consideration displayed in their bearing towards the patient. Your committee consider that an oral examination in surgery is a very valuable portion of the examination, and they recommend its inclusion by any of the bodies which do not at present hold it.

On the motion of Mr. TOMES, seconded by Mr. HODSDON, the report was approved.

National Insurance Bill Committee.

The PRESIDENT submitted the report of the National Insurance Bill Committee. The report detailed the communications which the committee had had with the Chancellor of the Exchequer. It set out further that at a meeting of the committee held on Nov. 29th, 1911, the Bill as amended in Committee of the House of Commons was considered. After discussion it was unanimously agreed that in pursuance of the Council's resolution of May 29th, 1911, the following representations should be made to the Government with a view of procuring further amendments of the Bill on report:—

I. That, as in the case of the Insurance Commissioners for England, it should be provided by Statute that the Insurance Commissioners for Scotland, Ireland, and Wales shall include duly qualified medical practitioners.

II. That statutory provision should be made for the appointment of Advisory Committees, including therein duly qualified medical practitioners, to assist the Insurance Commissioners in Scotland, Ireland, and Wales respectively.

III. That, in view of the large increase in the number of members who may now be appointed on Local Health Committees, it is urgently necessary that statutory provision should be made for the appointment of a larger number of medical practitioners on each such committee in each division of the Kingdom.

IV. That statutory provision should be made for the appointment of local medical committees in the other divisions of the Kingdom, including Ireland, corresponding to the provision made by Clause 58 for the appointment of such committees in England.

V. That Clause 16 (4), in so far as it entrusts the administration of "medical benefits" to existing organisations rather than to the Local Health Committee, as contemplated by Clause 16 (1), is not conducive to the efficiency of the medical service of insured persons, and should be deleted from the Bill; or at least that its application should be restricted to organisations actually in operation at the date when Clause 16 (4) was introduced into the Bill.

VI. That, notwithstanding the introduction of certain amendments relating to the treatment of insured persons in voluntary hospitals and other charitable institutions, there is ground for apprehension that the national scheme established by the Bill may operate so as seriously to impair the financial stability, and therefore the efficiency, of such hospitals and institutions; and that in view of the danger thus apprehended, steps should forthwith be taken by the Government to institute inquiries on this subject, and, if necessary, to propose legislation for the purpose of safeguarding the important interests, educational, scientific, and philanthropic, that are involved.

By request of the Chancellor, these representations were communicated to him on Nov. 30th, 1911.

The report was received and entered on the minutes.

The PRESIDENT then said: This report has been largely

the narrative of the steps that have been taken and the communications which have passed between us and the Government. Almost every stage of it has been made known to members of the Council by circulating a series of memoranda so that the Council has been able to keep pace with the successive steps in the negotiations which have taken place. The instructions given to the committee by the Council and its recommendations are set out in the report. After these are carefully considered by the Council now, I think it will be conceded that most of them appear to have been accepted. Since the committee was appointed the Bill has been before the Committee of the House of Commons and the process of transformation has not yet come to an end, and it is not quite possible for us to say whether further changes may not develop which would cause us to intervene again. For that reason I think that the committee should continue in being. A great many amendments were made in the House of Commons last night. I have not had an opportunity of seeing these amendments, and I cannot tell whether the suggestions which we made yesterday are now embodied in the Bill. In fact, it would be impossible to know whether they have been or not until we see the Bill printed as it emerges from the report stage. The newspaper reports are inadequate for the purpose of giving us the information. It will, however, be observed that two important points still remain not quite satisfactorily settled to the best of our information. One of these is the clause which continues to existing organisations the right to give medical aid and to have that medical aid recognised and subsidised as if it were medical benefit given to the Local Health Committee. Protest was made as to that, and what we are able to suggest is either that the provision should be deleted, or that if that is not done it should be limited in its scope so as to include only certain limited existing organisations which carry on *bonâ-fide* operations. The ground for introducing it before was that it was thought that certain vested rights ought to be respected. What was most desirable was that no new vested right should be made possible between this time and the passing of the Bill into law. I have reason to believe that the Chancellor fully appreciates that. He himself intends to introduce restrictions to that effect in a new clause. In the Bill as originally framed there was a grave doubt that our suggestions for the hospital treatment of insured persons were most inadequately provided for in the Bill. Practically the only recommendation as to the hospital treatment of insured persons was that the approved societies might give subscriptions or donations if they liked to hospitals. There was no indication that the Local Health Committee might make arrangements for such hospital treatment. Next, however, it was arranged that if an insured person was in hospital and had no dependents the sickness benefit went not to himself but to the Local Health Committee to be merged in the general fund. It was pointed out that the hospital was maintaining him and treating him, and it was not fair that the insurance fund should profit by his being so treated at the expense of a charitable fund. That is now met to some extent by an amendment which allows the Local Health Committee to make an arrangement by which the sickness benefit may be used to provide payment to the hospital in respect to his maintenance. Further, in the Bill as originally drafted sanatorium benefit was confined to sanatorium treatment for tuberculosis. Now it is possible for the Local Health Committee to contribute towards treatment for insured persons suffering from tuberculosis or any other disease in sanatoriums and other institutions. The Bill now makes possible that treatment otherwise than in sanatoriums or other institutions should be substituted by the Local Health Committee in respect of that disease. Notwithstanding that, your committee felt that the position of the voluntary hospitals was still in great danger, because they were still called upon in certain emergencies of acute disease to treat insured persons, without payment, except in the case where these insured persons had no dependents, and where there was a definite provision made that their treatment and maintenance should be paid out of the insurance fund. Of course there is the danger of which we are all aware, the danger of the possible diversion of the contributions of workmen and employers from the hospital to the insurance fund. The best that we could do was to point out that the danger will remain, and to ask the Government to make an inquiry as to the facts of the case and as to how the hospitals are to be affected under the new scheme, and if the inquiry proves these fears well grounded to ask that they should take legislative steps. That is the general result of our discussions yesterday on the National Insurance Bill. Under some pressure of time I had to formulate the matters on which representations had to be made to the Government with a view to procuring further amendments to the Bill on report. In conclusion, I move—

That the action of the committee be approved, and that it be requested to continue its efforts in the way of the improvement of the Bill.

Dr. MACDONALD formally seconded the motion.

The motion was agreed to without further discussion.

Conclusion of Session.

This concluded the business before the Council.

On the motion of Sir H. MORRIS, seconded by Dr. FINLAY, the President was thanked for his services in the chair during the winter sittings.

The Council then rose.

IMPERIAL UNIVERSITY CONGRESS.—Dr. Alexander Hill, formerly Master of Downing College, Cambridge, has been appointed secretary of the Imperial University Congress to be held in London in July, 1912.

HOUSING ACCOMMODATION FOR WORKERS AT THE ROSYTH NAVAL BASE.—Dr. Thomas F. Dewar, medical inspector to the Local Government Board for Scotland, and Mr. John Wilson, architectural inspector to the Local Government Board for Scotland, have jointly issued a report in the form of a Parliamentary white paper upon the house accommodation available for workers employed at Rosyth and upon the provision for sickness and accident. Exclusive of the engineering, clerical, and other members of the contractor's staff (about 100 in all), 1800 men were engaged on the works in May of this year, with a probability of more being employed as the work progressed. 34 per cent. of the workers are married, 57 per cent. single, and 9 per cent. boys. Although, perhaps, the housing accommodation is not all that could be desired, it is pointed out that except in a few cases overcrowding does not exist to an extent which would justify prosecution, though the reporters state that they have ample and abundant evidence of overcrowding in a minor degree. They also state that should an outbreak of smallpox occur there is no reason to anticipate that the measures already taken to provide for such a contingency would be inadequate or unsuccessful in cutting short an outbreak. Provision has also been made for accidents. The cost of medical attendance in cases of sickness among the workmen is met by a levy of 2*d.* a week on all employees. The report is published at His Majesty's Stationery Office at the price of 3*d.*

METROPOLITAN HOSPITAL SUNDAY FUND.—At a meeting of the council of the Metropolitan Hospital Sunday Fund, which was presided over by Archdeacon Sinclair and held in the London Mansion House on Nov. 30th, the secretary announced that Sir Ernest Tritton had been elected chairman of the Finance Committee. On the motion of Sir Ernest Tritton it was again decided to give to Sir Edmund Hay Currie an honorarium of £100 to enable him to take a much-needed holiday in the South of France. Archdeacon Sinclair moved the acceptance of the annual report, which stated that the receipts for the year amounted to £67,015. The church contributions—namely, £37,061—were £3717 less than in 1910. A sum of £8000 had been received from the executors of the late Mr. George Herring. Mr. William Herring had given a donation of £1000. Lord Cheylesmore seconded, and the report, which will be submitted to the annual meeting of the constituents of the Fund on Dec. 21st for adoption, was approved. Mr. Sydney Holland stated that in deference to certain expressed wishes he had decided not to continue the Sunday cinematograph exhibitions, notwithstanding the fact that his hospital would thereby suffer to the extent of £1200 a year. Sir Ernest Tritton called attention to the date of Hospital Sunday. He thought that the collection should be made earlier in the year than June. On the suggestion of Sir Henry Burdett it was decided to refer the matter to the executive committee for report. Hospital Sunday next year will be held on June 9th unless any different date is announced.

THE LANCET.

LONDON: SATURDAY, DECEMBER 9, 1911.

The National Insurance Bill.

DURING the past week the general opposition to the National Insurance Bill has not grown less in the medical profession. Numerous correspondents of our own, as well as published statements elsewhere, show that this hostility, although of the most varied kind, has one common origin—the feeling that the principles rather than the details of medical practice have received no proper respect. It is true that throughout the Committee stage of the Bill many other of the interests affected were found not to have been consulted or considered, and in consequence the Chancellor of the Exchequer showed himself willing to amend clause after clause in various directions. But in dealing with a highly organised profession like that of medicine, where the organisation consists largely in a differentiation of duties among men with common ideals, it must be a highly dangerous proceeding to try to force upon a substantial proportion of them a scheme which may profoundly modify their lives and livelihoods without an anxious and well-informed examination of all the facts drawn from unassailable sources. We have protested against the passage of the Bill, as it stood and as it stands, because it will turn the medical profession upside down without in any way securing a proportionate benefit to medicine or to the public. It is not beyond human ingenuity to devise a scheme to which, while the nation was enjoying the advantages of a National Insurance measure, the medical profession could heartily subscribe. But such a scheme should be inspired in its origin with real knowledge. The multiplicity of amendments in the section of the Bill dealing with medical benefits shows sufficiently that the National Insurance Bill was faulty in its inception, though it also testifies to the willingness of the Chancellor of the Exchequer to meet his critics in amity if not in substance.

The acceptance by Mr. J. SMITH WHITAKER, with the approval of the Council of the British Medical Association, of the post of Deputy Chairman of the Board of Commissioners to be constituted under the Act, must be regarded as a policy of compromise on the part of the Association, whose position will be puzzling to all of its ordinary members, and mortifying in the extreme to some of them. The governing body of the Association has throughout advocated making the best of the Bill, and has resisted the proposal that the medical profession, finding the scheme unworkable, should have nothing further to do with it. The line of compromise taken has not been in response to any general mandate of the members, but rather to the feeling of the Council that a policy of making good terms under the Bill was supported by a majority, either in number or weight, among the constituencies. Throughout the summer, therefore, negotiations have been taking place between the Association and the Chancellor of the Exchequer, the field of debate being presumably the six cardinal points on the granting of which depended the adherence of the Association to the Bill. At the meeting of the Representative Body of the Association held on Nov. 23rd and 24th in London, not without many dissentients however, the Representatives decided to take the advice of a report to them from the Council, and to continue through the Association a conditional support of the Bill, although the six cardinal points had not been granted. At the same time the determination to insist upon these points was re-affirmed by what was termed a "Declaration with regard to Future Action as to the Cardinal Principles," the resolution in question being to the effect that the British Medical Association would use every possible means to ensure that no medical practitioner should undertake the attendance and treatment of persons insured under the Bill save in accordance with the six cardinal principles. The situation, therefore, does not differ now much from what it was six months ago, save in the important fact that the medical secretary of the Association, with the approval of the Council, has been placed in a high position on the small and supreme body of Commissioners to whom will fall the administration of the Bill.

Mr. SMITH WHITAKER has proved himself to be an indefatigable worker and an accomplished advocate of the policy of the Association, and his knowledge of the medical side of the Insurance Bill in all its permutations and combinations is probably unrivalled. To a large extent he has been the mouthpiece of the Association during the past six or seven eventful months. His transference, therefore, from the position of chief advocate of a policy of resistance to the Bill until certain concessions are made, to the position of Deputy Chairman of the Commissioners is startling. In his new position his freedom of speech and of action are necessarily curtailed. Hitherto he has spoken for the large section of the Association whose opinions have coincided with those of their leaders; henceforward he will be one of a small group of judicial officers whose business it will be to secure the smooth working of the Act and to dispense even justice between the most conflicting interests. That he will do his utmost to uphold the policy which he has already expounded with such zeal and ability may be taken for granted. He knows the arguments for that particular course and the general justice of the medical protests; but will he have power to enforce his views? The motives of the Council in approving his appointment have been excellent; but while reflections upon the integrity of the Council are ridiculous those upon their judgment have force. They have endorsed, by sanctioning Mr. SMITH WHITAKER'S new position, the working, not the principles, of a measure dangerous to the medical profession, one whose influence has not been gauged and whose promise is full of ill omen.

The General Medical Council and the Sandow Curative Institute.

THE proceedings taken by the British Medical Association before the General Medical Council with regard to the conduct of three medical practitioners in associating themselves in their professional capacity with the "Sandow Curative Institute" have reached a further, but not a final, stage at the recent session of the Council. The name of one of the three gentlemen referred to, Mr. M. E. A. WALLIS, was at the session of last May removed from the Medical Register. Another, Mr. C. E. TRIMBLE, in whose case judgment was postponed in May to allow him to reconsider his position, has now produced evidence to show that he is practising his profession in Wales, having entirely severed his connexion with the Sandow Institute, and with regard to him all proceedings are consequently at an end. The third practitioner affected, Mr. J. R. WALLACE, had the same opportunity afforded to him as Mr. TRIMBLE, but took a different course. He remained associated with the Sandow Institute, and before the Council at its recent session this was frankly admitted on his behalf by Lord ROBERT CECIL, K.C., who stated that the institute had discontinued advertising for the purpose of procuring patients or with the promise to cure disease, that Mr. WALLACE had now absolute control and direction of the institute, and that he accepted full responsibility for everything done in it. This was borne out by the personal evidence of Mr. WALLACE, who stated that he saw all patients and prescribed the treatment to be pursued, being entirely responsible for that treatment. He also said that Mr. SANDOW still saw cases occasionally but undertook no responsibility with regard to their treatment, and that the new arrangement thus described constituted a complete change from that which had prevailed before. This being clearly an effort made by Mr. WALLACE and the Sandow Institute to bring the practice of the former within lines consistent with the well-known principles of medical ethics the Council accepted it as such, so far as the information made that possible. That is to say, the Council again adjourned the case of Mr. WALLACE until the next session in order that he might then produce more satisfactory evidence regarding his professional conduct, such evidence, as was suggested, to be that of medical practitioners. This we interpret to mean that in the opinion of the Council the association of Mr. WALLACE with the Sandow Institute might in the working prove blameless, but that only from observation of the actual practice that might follow professions of amendment could it be ascertained whether the features which rendered the Sandow Curative Institute objectionable had finally disappeared.

At this stage the matter might have rested for another six months, and, strictly speaking, it does so rest, so far as the consideration to be afforded to it by the General Medical Council is concerned. From announcements made through the medium of the daily press by Mr. EUGEN SANDOW, however, and from a letter addressed by Mr. WALLACE to the Registrar of the General Medical Council, we gather that the more recent conditions described by Mr. WALLACE in his evidence—upon which Lord ROBERT CECIL relied in addressing the Council as constituting, according to his case, a course of conduct beyond reproach—are not to be maintained. The statement referred to as made by Mr. SANDOW was published in the newspapers of Dec. 1st, where it may be read. It describes the decision of the Council as a refusal of "plain justice," and as suspending the sword of the Council's displeasure above Mr. WALLACE'S head for a further period of six months, and it concludes as follows: "As apparently there is no means of satisfying that autocratic body, the General Medical Council, and I fail to see any reason whatsoever why the British public should be deprived of the benefit of my medicineless treatment, to which so many thousands have testified, I intend to leave the final judgment of the rights and wrongs of this mysterious offence against an obscure and unreasonable tradition to be decided by the British sense of justice and fair-play, and from now onwards shall place my Curative Institute at St. James's-street at the disposal of every sufferer by making known, through the medium of the Press, that such an institute exists." Mr. WALLACE, in his letter to the General Medical Council, protests generally against the course adopted by the authoritative body of the profession, and in particular against what he alleges to be an ignoring of evidence of similar practices in connexion with other institutions employing medical men. He writes: "I desire to state now, rather than wait until the expiration of six months hence, that I intend to continue my work. If the General Medical Council consider that they are entitled to resolve that this constitutes 'infamous conduct in a professional respect' on my part, then I leave them to direct the removal of my name from the Medical Register; but I reserve my right to question their decision, and I trust they will take an early opportunity of passing some resolution, so as to enable me to do this without unnecessary delay." We gather from this that when the case of Mr. WALLACE comes again before the General Medical Council there will necessarily be evidence of a fresh course of conduct differing from that described at the session recently concluded, and again from that which prevailed before last May, and that any decision come to which is adverse to Mr. WALLACE will be called in question, so far as this may be possible, in the High Court of Justice. In these circumstances we have referred above to the present stage of the proceedings as not being final, and we almost necessarily refrain from commenting upon the position taken up by Mr. WALLACE and Mr. SANDOW.

We may, however, remind our readers of a few of the facts not in dispute which were before the General Medical Council last May, and upon which its decisions were then passed with regard equally to all the three medical men implicated. With the side of the business of Sandow, Limited, which is connected with the promotion of muscular development and the increase of physical efficiency in those who present themselves as clients of a noted "strong man," the medical profession is not immediately concerned. Mr. SANDOW has cultivated an extraordinary muscular development in himself, and if others try to emulate him by seeking instruction from him, his position with regard to

his clients and pupils is not greatly different from that of the professional athlete who trains amateurs for rowing, boxing, running, or other branches of athletics. The case which was brought before the General Medical Council as to the connexion with the institute of three registered medical men had nothing to do with such an aspect of Mr. SANDOW'S business. In addition to giving instruction in dumb-bell exercises and other methods of increasing muscular power, and as a later development, Sandow, Limited, has sought to derive profits from a branch of its business described as the "Sandow Curative Institute," and from what it has described in advertisements as "curative physical culture." As evidence of this claim to be curative—that is to say, to treat and to heal disease—one of the pamphlets or advertising leaflets issued by the institute and laid before the General Medical Council recommended all sufferers from the complaints mentioned in it to place themselves unreservedly in the advertisers' hands, the complaints mentioned including "acute bronchitis." It was stated as a matter of history, and was not disputed, that the practice of the institute had been at one time to send prospective subjects to private medical practitioners for examination in order to ascertain whether any physical weakness rendered the treatment proposed for them inadvisable, but that as a matter of greater convenience the medical men before the Council had been engaged as officers of the institute to make such examinations as indicated above upon its premises, but that their employment was not for the purpose of prescribing physical exercises or any other form of treatment for those consulting them. It was not disputed by the three gentlemen whose conduct was under review that sundry advertisements issued by the institute had appeared to them to be objectionable. On the other hand, it was not suggested by those who laid the facts before the General Medical Council that the position and conduct of the three medical men complained of had not been frankly and accurately described by them at the inquiry and before it, or that they had originally intended to transgress the rules of conduct which should be observed by members of their profession, or that the statement made by Mr. WALLIS was untrue when he said that during his service as medical officer of the institute a great many medical practitioners had visited it and had brought their patients there to undergo treatment. Upon the facts which we have briefly summarised above were based the propositions advanced before the Council by Mr. SMITH WHITAKER on behalf of the British Medical Association that (1) the Sandow Institute undertook the treatment of disease; (2) that the gentlemen proceeded against were employed by the institute in their professional capacity and were aiding and abetting in the carrying out of the treatment of disease by the institute; (3) that the institute had recourse to an extensive system of advertising for the purpose of attracting patients; and (4) that the treatment of those patients at the institute was entirely prescribed by Mr. SANDOW, an unqualified person.

We believe that we have correctly stated above enough to show exactly what the issues have been which the General Medical Council up to now has had to consider and decide, and as to which members of the medical profession will form their own opinions. Mr. SANDOW and Mr. WALLACE have submitted them to the public, a tribunal not always unprejudiced and not entirely competent to appreciate the principles upon which decisions of the General Medical Council upon matters of professional conduct are based. Both have also intimated that before the case of Mr. WALLACE comes again before the General Medical Council a different practice will have been in use, as to which, presumably, there will be no secret, and as to which evidence will, if desired, be forthcoming. Mr. WALLACE has added to this the information that he desires without delay to test the legality of the Council's attitude towards the Sandow Curative Institute and himself. If by an appeal to judicial authority upon a point or points of law a question directly affecting the ethical standards of the medical profession, and of no small importance to the public, can be finally determined, we feel sure that none will welcome the occasion more than the profession at large or the Council, which Mr. SANDOW denounces as autocratic, and which Mr. WALLACE accuses of ignoring evidence tendered on his behalf.

Annotations.

"Ne quid nimis."

DREAMS.[1]

SOMEONE has said that a Philistine family can be defined as one of which all the members tell each other their dreams when they meet at the breakfast table. Yet the subject of dreams has from time immemorial exercised a fascination over the intellectual and the illiterate alike, although the attitude of mind in which it is approached may vary enormously. Some will see in the tragic poignancy of a dream a revelation, from an ultra-mundane source, of things to come, while others will attribute similar phenomena to unusual visceral activity consequent on an injudicious meal. The late Sir Samuel Wilks, Mr. Ellis reminds us, once made the acute remark that "the dreamer merely forms a mental picture, and the description of it he calls his dream." It is in the process of describing dreams that expansions are liable to occur, that dream incidents are prone to be altered in accordance with conscious memories, that coloured interpretations of the dream reality are apt to vitiate its simplicity. For years Mr. Ellis has made it a practice to write down in the morning the plain unvarnished data of his dreams and to adopt the introspective method of dealing with these data. He has therefore been able to satisfy himself that the facts as given in the volume before us are reasonably accurate, and has confined his discussion to what may be called the problems of normal dreaming. The reader will find that Mr. Ellis's dream experiences are very like his own, though curiously enough there appears to be no reference to the "inadequately clothed" dream with which most are familiar. Many of the phenomena receive at Mr. Ellis's hands ample explanation on perfectly simple grounds, to the achievement of which his psychological knowledge and scientific spirit alike contribute. The symbolism of dreams is duly exemplified, and although the author is ready to admire the profound and daring interpretations of dream symbolism furnished by Professor Freud, he is unable to follow him into the devious and puzzling maze of wish-fulfilment.

[1] The World of Dreams. By H. Havelock Ellis. London: Constable and Co. 1911. Pp. 238. Price 7s. 6d. net.

It seems clear that the phenomena of dreams are well worth studying for the light they cast on certain pathological processes of a non-organic sort. In dreams the illusion of false recollection, the sensation of "déjà vu," is fairly common, especially in the hypnagogic state, as it is in waking life. Mr. Ellis offers a theory to account for it which is deserving of serious consideration, but perhaps he does not fully appreciate the extent to which the phenomenon occurs in association with certain idiopathic epilepsies, organic lesions of the uncinate gyrus, and other diseases of "functional" type. In the aura of certain epileptiform seizures it not infrequently happens that surrounding objects lose their "familiarity" or "reality," and that this familiarity or reality is transferred, as it were, to the place and circumstances in which the patient, not yet fully unconscious, imagines himself to be. Hence these seem so familiar that he experiences a keen sensation of "having been there before"—in other words, he has an illusion of "fausse reconnaissance." Many neurasthenic patients complain of the "unreality" of their surroundings, as hysterical patients do of parts of their own body, and it may be that "reality" is an attribute that is detachable. The sense of impending trouble, the fear of impending death, of which Mr. Ellis supplies illustrations from the dream world, is a common accompaniment of vaso-vagal attacks—the "affolement bulbaire" of French writers; and it may be questioned whether one of his examples is not drawn from an ordinary case of so-called cardiac neurasthenia. The tendency to magnification that is often well marked in dreams is paralleled by the disturbances of cœnæsthesia, of which many instances have been recorded. A patient in the throes of a vaso-vagal attack imagined that her head had shrunk to a minute size, while her limbs were giant limbs moving through an enormous range. If such phenomena occur in association with definite functional disturbance of medullary centres, there is no obvious reason why some such explanation should not hold good for analogous experiences when the cortex is asleep. One or two of Mr. Ellis's statements are open to some minor criticism. The sensory aphasic does not always think his nonsense is quite clear and reasonable. On the contrary, his distress at being unable to express himself clearly is sometimes striking. Liepmann was the originator of the modern conception of motor apraxia, not Pick; in Liepmann's ideational apraxia (identical with Pick's ideomotor apraxia) plans are defective, not because they are "not supervised by the higher centres," but because these higher centres themselves are not functioning normally. This book is a charming contribution to the literature of dreams. All who are interested in "the stuff that dreams are made of" will ead it with relish and profit.

THE RELATION OF EPILEPSY TO LEFT-HANDEDNESS.

IN the August number of the *Monatsschrift für Psychiatrie und Neurologie* is a communication from Dr. G. Steiner, based on material obtained in the Psychiatric and Nerve Clinic in Strasburg, relating to certain associations between idiopathic epilepsy and left-handedness. The article contains statements which, if corroborated by subsequent investigation, may turn out to be somewhat far-reaching in their effect. The student of epilepsy is aware of two definite tendencies in the prosecution of the subject under modern conditions of knowledge: there is first the tendency to widen the borders of the disease, and to include therein such phenomena as faints, vagal attacks, migraine, vertigo, narcolepsy, night terrors, &c., and, on the other hand, there is the tendency rigorously to exclude certain morbid conditions which occasionally reveal themselves by episodic phenomena in the form of epileptiform convulsions. Unverricht's myoclonus-epilepsy, psychasthenic convulsive attacks, the epilepsy of infantile cerebral lesions, ought to be considered as distinct from true epilepsy. In this connexion it is desirable to abandon such terms as arterio-sclerotic or alcoholic epilepsy, and to employ the more correct expressions epileptiform arterio-sclerosis and epileptiform alcoholism. Desirous of studying more closely the distinguishing feature of genuine cases of idiopathic epilepsy Dr. Steiner, whose work is based on some little-known investigations of Lombroso, Tonini, and Redlich, has been led to the conclusion that left-handedness occurs with great frequency in the families of such cases. Lombroso was the first to note this apparent frequency in epileptics themselves: of 176 cases 10 per cent. were left-handed. Tonini found the phenomenon in no less than 40 per cent. of his cases. Redlich noted 22 left-handed patients out of 125 epileptics—that is to say, 17·2 per cent. Dr. Steiner, however, seems to be the first to point out that in the families of right-handed epileptic patients left-handedness often occurs in normal individuals. His figures are based on 57 cases of pure idiopathic epilepsy in which the patients themselves and their families were subjected to careful examination from this special point of view. In 40 cases left-handedness was noted in the family; 11 cases were themselves left-handed. Left-handedness in the family with right-handedness of the patients was noted in 70 per cent. of cases; left-handedness of the patients with right-handedness only in the families, in 15½ per cent.; left-handedness in the patients and also in the families in 3½ per cent.—a total of no less than 89·5 per cent. of cases in which left-handedness occurred in the patient or his family. Such figures are sufficiently striking. When it is remembered that the average percentage of left-handed individuals in the community at large is only about from 2 to 5, the data furnished by Dr. Steiner are indeed remarkable. The interpretation of their import is not easy. It is, of course, too large a percentage to be regarded merely as an accident. On the other hand, complacently to characterise this left-handedness as one more of the stigmata of degeneration so common among epileptics is scarcely justifiable. Notwithstanding the contention of some that stammering is more frequent among left-handed people, and the opinion of Havelock Ellis and others that left-handedness is commoner in degenerates than in normal individuals, it cannot seriously be held that left-handedness is of itself a sign of degeneracy. A consideration of the degrees of left-handedness, and of the place it takes in the history of the race and the child, precludes such a view. Dr. Steiner has a hypothesis to account for the apparent predominance of the condition in his epileptics, and more particularly their families—viz., the existence of an inherited tendency to a pathological disturbance of the normal cerebral mechanism, whereby for all practical purposes the left hemisphere leads the right. In normal left-handed individuals certain parts of the right hemisphere lead the left. In epilepsy there is a conflict between this inherited tendency to left-handedness and a congenital disposition to right-handedness.

LOCALISED CONFLUENT VARICELLA.

THE eruption of varicella is usually generalised and non-confluent. In the *Gazette Médicale de Paris* of August 2nd M. Chatin and M. R. Rendu have reported a rare case in which a localised confluent eruption occurred. A child was taken to hospital with an eruption dating from the previous evening. On first sight it seemed to be a patch of eczema covering the whole of the front of the chest and showing a well-marked border. On the back was a similar patch but with the eruptive elements less close together. This localisation suggested the application of some irritant. Indeed, the

patch on the chest recalled the confluent miliary eruption produced by the application of croton oil. But the mother denied that any application had been made. On further examination the typical disseminated vesicles and pustules of varicella were found between the two patches. Similar but less typical lesions, with their characters altered by confluence, could be observed in the patches mentioned. There were also some well-marked discrete lesions of varicella on the face and limbs. What was the cause of confluence of the lesions on the chest and back? It was noticed that in the position of the patches the skin had a slightly yellowish tint. On pressing the mother she admitted that she had applied tincture of iodine there three weeks previously. Evidently this was the cause of the localisation and confluence of the eruption. Analogous facts have been recorded, not only in the case of varicella, but also in variola and generalised vaccinia. In a work on variola, published in 1870, J. Rendu described greater confluence of the eruption on irritated surfaces, particularly on those produced by blistering. Curschmann attempted to localise the eruption of varicella on the limbs by the application of tincture of iodine in the hope of diminishing its intensity on the face, but without success. M. Chatin and M. Rendu refer to the case of an infant who had chronic eczema localised on the chest, back, and upper limbs. The eruption of generalised vaccinia appeared only on the eczematous surface and was so aggregated that it resembled confluent variola. With regard to varicella, Henoch has reported a case in which the eruption was more profuse on the side on which a child always lay. The eruption of varicella has been observed to be more abundant on the surface of an abscess. Galliard has reported a case very similar to that narrated above. A little boy's back was painted with tincture of iodine at the time when the eruption of varicella appeared. The region painted was the seat of multiple miliary vesicles and of numerous vesicles remarkable for their large size, while on other parts the eruption was discrete.

POLIOMYELITIS AND PUBLIC BATHING.

Dr. F. W. Alexander, medical officer of health of Poplar, has sent in an interesting communication arising out of a paper recently read by Dr. F. E. Batten before the Metropolitan Branch of the Society of Medical Officers of Health on Oct. 27th upon "Acute Epidemic Poliomyelitis."[1] Dr. Batten said that "in the Massachusetts epidemic careful inquiry was made into 150 of the 923 cases which occurred in the year 1909," and that "the result of these investigations do not bring into prominence any common factor. It is, however, noteworthy that of the 150 cases 62 were swimming or wading in water more or less contaminated by sewage before the attack." These remarks particularly appeal to Dr. Alexander in view of the remedial methods of bathing water purification in which for some considerable time he has interested himself at Poplar. "In September, 1909," says Dr. Alexander, "in two somewhat lengthy reports, and in my annual report for the year 1909, I pointed out to the baths and washhouses committee of the Poplar Borough Council the horrible dangers of public swimming baths, *inter alia* mentioning how quickly swimming-bath water changes its pristine sweetness even after being used only by a few bathers, particularly so in warm weather, and becomes after use by a number of bathers nothing more or less than diluted sewage, and this condition exists often before the first day's use is finished. The formation of slime in the bath water was also mentioned and commented upon at length. Mr. Pearce, medical officer of health of Batley, in an article contributed to THE LANCET showed that there is manifest danger of infection through the use of polluted bath water." Dr. Batten in his paper stated "that during the last decade acute epidemic poliomyelitis has become widespread in acute epidemic form throughout Northern Europe and America." He also states: "In the Northern Hemisphere the disease always has the greatest prevalence during the months of July, August, and September ..... poliomyelitis is prevalent during the summer months in London, and especially during August and September ..... that poliomyelitis is communicated from person to person probably by means of secretion from the nose and mouth," and that "it may be said that the virus of poliomyelitis has not yet been seen under the microscope and has not yet been cultivated." He also states that the disease has an incubation period of probably less than six days in man, although experimentally the incubation is between 8–12 days, and that there are striking instances where a school has been shown to be the centre for the spread of infection. Dr. Alexander accordingly contends as follows: "As it is during the months of July, August, and September that swimming-baths are mostly used, it has occurred to me that it would be of considerable interest to bacteriologists to take into consideration the possible connexion of polluted swimming-bath water, more especially the slime which forms at the bottoms of the baths, and the disease and possible determination of one of the causes of poliomyelitis, and to find out if such slime plays any part in the cause of poliomyelitis, and at the risk of telling plain truths to see also if lice (which have been found in the towels after use and in the dressing-boxes) take any part." He explains that he cannot produce a specimen of the slime from the Poplar swimming-baths, as those baths are kept free of it by the addition of electrolytic fluid manufactured by the borough council and added in the proportion of 1 part of chlorine to 2,000,000 parts of the bath water. But commenting on Dr. Batten's statement that the virus of poliomyelitis is a living organism which would pass the finest porcelain filter, he adds, quoting from his annual report for the year 1909: "Where filtration and aeration are carried out in public baths it is noticed the filters become covered with distinctly offensive slime occasioning much and continued cleansing of the filters; and then, again, unless the bath is entirely emptied and cleansed slime still remains at the bottom. In any inquiry into the possible cause of an outbreak of poliomyelitis or polioencephalitis it would be of public interest to find out if patients had frequented a swimming bath within a specified period of the first appearance of the disease, as there must be many swimming baths and outdoor public bathing lakes and ponds, &c., where no precautions for keeping the water pure are adopted." Dr. Alexander certainly brings an interesting point to the attention of sanitarians.

[1] The paper read by Dr. F. E. Batten is published in "Public Health" for November, 1911.

THE USE OF SALVARSAN IN MENTAL DISEASES.

Dr. R. Dods Brown, senior assistant physician to the Royal Edinburgh Asylum, describes, in the *Review of Neurology and Psychiatry* for November, his experiences with salvarsan in 17 cases of mental disease of a syphilitic, parasyphilitic, and non-syphilitic nature. The exact record is as follows: one case of insanity from cerebral syphilis, five cases of general paralysis, five of dementia præcox, two of delirious insanity, two of chronic delusional insanity, and one each of acute melancholia and acute mania. Remarkable improvement took place in the first of this series, a man aged 41 who had contracted syphilis 11 years previously, and presented when under observation

definite nervous and mental symptoms of intracranial syphilitic disease. Intravenous injection of 0·2 gramme was followed in 17 days by a further dose of 0·1 gramme. After the first injection the lymphocytic content of the cerebro-spinal fluid fell from 30 to 7·6 per cubic millimetre. Three of the cases of general paralysis were treated intravenously, and two intramuscularly. In all five cases the blood pressure rose after the injection, and there was in addition a relative leucocytosis in the blood. Clinically, no definitely favourable results were obtained in these cases, although in three some improvement was noted, but whether this is to be attributed to the special treatment is doubtful. It is noteworthy that the use of salvarsan in these general paralytic cases made no difference to the Wassermann reaction, which remained positive in the blood and cerebro-spinal fluid, yet a great reduction in the lymphocytic content of the latter took place in several of the cases, in one instance falling from 40 to 7·6 per cubic millimetre. The proteids remained unchanged. The results in the dementia præcox cases were practically negative, except that "in two cases the patients have become more accessible and responsive than they were before." In the other six cases where salvarsan was administered empirically no unequivocal results followed; it is true the two cases of delirious insanity apparently improved. One of the patients suffered from acute recurrent mania, and after receiving the injection she passed through two attacks, both of which were shorter and less severe than any during the previous two years. There was a very marked decrease in the amount of urine excreted in two cases. In one of these it fell from an average of 44 ounces to 16 ounces for four days. Speaking generally, the syphilitic cases gave a more pronounced temperature reaction and a more definite increase in leucocytes after the injection than the others, but the cases which reacted most did not show the best results. The value of the drug in mental disease is still problematical. Recoveries such as can be obtained in syphilis cannot be recorded; Dr. Dods Brown, however, considers that in the majority of his cases the physical health benefited materially.

BILIARY COLIC AND CARDIAC MURMURS.

VARIOUS physicians have drawn attention to the fact that cardiac disease and cholelithiasis are prone to coincide in the same patient, but it has not been possible to prove anything beyond a coincidence or to define an etiological relationship between the two lesions. Various theoretical suggestions have been advanced; some have considered that the cardiac lesions are endocardial and depend upon infective agents introduced to the circulation through the biliary tract, while others have regarded the condition as a myocardial one caused by infection or intoxication from the gall-bladder. Among the latter group of observers is Dr. David Riesman, of Philadelphia, who has written a short note to the *American Journal of the Medical Sciences* for November, 1911, stating that in 56 cases of gall-stone disease seen in his private practice 6, or 10·7 per cent., showed cardiac murmurs. In five of these the diagnosis of cholelithiasis was completely established by operation or otherwise. He thinks that if all patients with biliary colic were examined during or soon after the attack a higher percentage of murmurs would be registered. The murmur heard is that of mitral regurgitation; it is usually associated with some cardiac dilatation and disappears when the attack is over or after an operation if one is undertaken. He describes the case of a woman whose paroxysms of colic left her not merely with a bruit but with a liability to attacks of cardiac dilatation with dyspnœa and cyanosis; these symptoms and signs disappeared after an operation in which a stone was removed from the common bile-duct. Riesman suggests that the relationship is a direct one; the gall-bladder is the seat of an infection whose toxins injure the myocardium, while the rise of blood pressure which occurs during attacks of biliary colic dilates the left ventricle and induces a temporary insufficiency of the mitral valve. The moral is that the presence of a cardiac murmur furnishes no contra-indication to operation for the cure of cholelithiasis, but rather the reverse.

NOVEMBER AT HOME AND ABROAD.

NOT the least of the items that can be placed to the credit of November of this year is its freedom from fogs. Not once did London experience serious inconvenience, and rarely was the atmosphere so thick as to justify the term moderate or light fog. Another good point was its rainfall. Much rain was needed in these islands to compensate for the enormous shortage left by the droughty summer, and the heavy and frequent rains of November have done much to make up the deficiency. In the metropolitan district the amount of rain was about three-quarters of an inch in excess of the average for November, and varied little in the different localities. At Kew, and also at Hampstead and Greenwich, the total was 3·4 in., and at Westminster 3·1 in. Over a very large portion of the kingdom the excess on the average was much more pronounced, especially in the county of Kent. But although the weather was decidedly wet and unsettled it was also sunny for the time of year. Very little is expected in the matter of sunshine in November even on the south coast, and still less in London. The total number of hours over the country generally was, however, above the normal. In the suburbs of London the sun shone brightly for an aggregate of about 55 hours. Nearer the centre the figure decreased to 39 hours at Westminster, while in the City it only amounted to 28 hours. The figure at Westminster exceeded the average by 44 per cent. and that in the City by 27 per cent. The temperature of the month differed little from that of the average November in the British Isles, sometimes being some way above it and at other times below it. In the metropolis the warmest afternoons were at Westminster and the more central districts, where the shaded thermometer rose to 50° or above on 18 days, and the mean of the maximum readings was 51°. At both Kew and Greenwich the corresponding mean was 49° and at Hampstead not higher than 47°. The mean daily range of temperature was less at Hampstead than elsewhere, the figure being 8° at the northern suburb, 9° at Westminster, and 10° at Kew and Greenwich. Not one severe frost occurred in any part of the metropolitan area. At Hampstead the sheltered thermometer descended to 32° or below on no more than four nights, and the same figure was recorded at Greenwich, while at Kew and Westminster the respective figures were 3 and 2. The general wind current was from between south and west and its average strength rather high. Only one spell of wind between east and north occurred, the period being from the 20th to 26th. The weather on the continent underwent considerable fluctuations, but the southern regions were generally much warmer and finer than the most southern parts of these islands. At Paris, however, the climate was very little superior to that in London. Rain fell on 14 days and yielded a total of 2·07 in., and as many as 13 days were sunless. Altogether the sun shone brightly for 59½ hours, a figure very little higher than that in the suburbs of London. Its temperature considered as a whole was slightly colder than London, although on a few days it was warmer. On only 15 afternoons did the shaded thermometer ascend to 50° or above. On the Riviera the temperature was about 10° higher than at Paris and in London, the sheltered thermometer recording 60° or above on 15 days, and the average night being warmer. There

were several spells of cloudy skies, but rain was not so frequent as it often is during November, and rarely very prolonged or heavy. The most rainy periods were on the 8th and 9th, and towards the end of the month. The wind was strong occasionally in exposed situations, but as a rule there was nothing stronger than a gentle breeze. At Biarritz the weather was somewhat more variable and also a little cooler. The thermometer rose to 60° or above on only 12 afternoons, while on several occasions it failed to rise much beyond 50°. Except when rainy, however, the sky was very rarely overcast. As is usually the case at Biarritz when the weather is stormy on the Atlantic and in this country, the wind was frequently very strong from the westward and the sea high. Italy differed little from the Riviera, except that its temperature in the inland districts of the north was much lower and that of the more southern regions higher. The Mediterranean islands and the coast of Algeria experienced a temperature about equal to that of early June in the south of England. The sheltered thermometer rose to 70° or above on several afternoons, and generally to above 65°, while under the influence of the sirocco about the middle of the month it went to 80°. Rain was not frequent for November, but strong winds from various quarters were often experienced, sometimes locally, and sometimes over a very wide area.

TUBERCULIN IN PULMONARY TUBERCULOSIS.

THE recent puffing of tuberculin as an infallible remedy for practically every form of pulmonary tuberculosis is as great a danger to the good name of this valuable remedy as was its reckless dosage in the early days of its existence. A sober analysis of the results obtained by this treatment is therefore most welcome at this stage, and Dr. O. Helm's report in a Danish medical journal, *Hospitalstidende*, on his experience of about 300 phthisical patients treated over a period of five years, is a valuable contribution to the subject. In the period 1906–07, 63 patients were treated with old tuberculin in addition to sanatorium treatment. Very early cases, in which the diagnosis of phthisis might be challenged, as well as very advanced cases were excluded. Götsch's method of administration was adopted, the initial dosage being 1/10 mgr. The treatment was soon given up in 18 patients who reacted unsatisfactorily with increased dosage of tuberculin. As a matter of fact, it is hardly fair to exclude these 18 from the analysis of the results three years later. But with this exception the writer seems to have put the case for and against tuberculin very fairly. Most of the patients exhibited reactions which were, however, seldom excessive. After a lapse of three years the result of the treatment on the remaining 45 was as follows: 84·4 per cent. were "cured," the disease was active in 6·6 per cent., and 9 per cent. were dead. This satisfactory result was, however, partly due to sanatorium treatment, and for this reason, as well as on account of the small number of patients treated, no definite conclusion can be drawn, though in certain individual cases the writer was impressed with the efficiency of the treatment. Encouraged by the favourable reports of new tuberculin (bacillary emulsion) as compared with old tuberculin, the writer gave it subcutaneously to 53 patients, in all of whom the diagnosis of phthisis was certain. Nine patients discontinued the treatment for various reasons. Of the remaining 44, 16 were in Stage I., 20 in Stage II., and 8 in Stage III. of the disease. No very severe or apparently hopeless case was included. None of the patients were febrile, the general condition was invariably good, and there was no case complicated by cardiac or renal disease. In fact, the type of patient was one that usually improves under sanatorium treatment, but without complete arrest of the disease. All but three had tubercle bacilli in the sputum. Twenty-four patients presented no febrile reaction at all, and a violent febrile reaction necessitating the abandonment of the treatment occurred only once. The disease was "cured" in 4, 19 were improved, 12 were stationary, and 9 became worse. More than a year later 7 patients were dead, 15 were unfit for work, 4 were fit for light work only, and 18 were "cured." This result compares unfavourably with the results in the same class of patient treated by sanatorium methods only. It would appear that substantial advantages from this form of tuberculin treatment in phthisis are absent. Bacillary emulsion has been extolled as an antipyretic, and Dr. Helm therefore administered it to 10 patients who, in spite of sanatorium treatment, remained febrile. Anatomically the disease was not very extensive, but in all profuse expectoration and numerous tubercle bacilli were present. Very small doses were given at first, and the largest final dose did not exceed 2·5 mgr. The treatment lasted on an average 55 days, the injections being given at intervals of from three to four days. In no case was the fever diminished by the treatment, and a year later 5 patients were dead and 5 were still unfit for work. The Russian tuberculin "endotin" was given to 10 sanatorium patients, 4 of whom were in Stage I., 4 in Stage II., and 2 in Stage III. of the disease. Gabrilowitsch's method of administration was adopted. Nine of the patients exhibited a reaction when the larger doses were reached. The average increase of weight was 10 lb. Tubercle bacilli were found in as many patients at the end as at the beginning of the treatment, which lasted on an average 93 days. The immediate results in 9 reported cases were: improvement in 4, no change in 2, and progress of the disease in 3. But a year later 6 were "cured," 2 were fit for light work, 1 was unfit for work, and 1 was dead. These results are interesting, although the material is too scanty for any conclusive inferences to be drawn. It must be pointed out that those results obtained with new tuberculin differ considerably from those reported by other observers, especially in certain German sanatoriums.

ŒDEMA INDUCED BY COMMON SALT IN CHILDREN.

IT is now well known that in patients suffering from nephritis or from failing compensation in heart lesions the presence of common salt in the diet exercises an important influence upon the occurrence of œdema, and a "salt-free" diet is recommended, more especially by French physicians, in the treatment of œdema resulting from these conditions. That the same phenomena may be observed in infants and children who are not the subject of renal or cardiac disease is less generally known. The matter is discussed in an interesting paper published in the *Münchener Medizinische Wochenschrift* of Nov. 21st by Dr. Franz Hamburger of Vienna. He states that in infants who are the subjects of acute or chronic disturbances of nutrition excess of salt may cause œdema, even when there is no evidence of disease of the kidneys or heart, and he records a case of similar nature in a boy 5 years of age. The child suffered from chronic digestive disturbance and neurasthenia. He was of emaciated and miserable appearance and was sent for a "cure" to Carlsbad, where he improved considerably. Shortly after his return he was brought to Dr. Hamburger, who found general œdema and marked swelling of the prepuce. The urine was free from albumin, and on examination a faint and variable systolic murmur was heard, which had often been observed before and was not regarded as indicative of any cardiac lesion. On inquiring into the diet taken by the child Dr. Hamburger found that the broth which the child had been given was

very salt, and that it had caused considerable thirst. He ordered a diet poor in salt, and in three days the œdema had lessened considerably, the child having lost 2¼ kilogrammes in weight during that time. The child is now completely sound and in good health. Dr. Hamburger has since found that in many children who are emaciated or cachectic or otherwise damaged by some illness the administration of common salt will lead to œdema, although the heart and kidneys may be healthy. Some cachectic children develop diarrhœa after the administration of salt, in which case œdema does not occur. These observations are of considerable interest and merit careful notice. As Dr. Hamburger points out, they suggest that in cachectic œdema the causal factor may be some agency which disturbs the normal metabolism of salts. They also indicate a definite line of treatment in some cases of obscure œdema in children, particularly those of supposed nephritis without albuminuria.

SOME SOCIAL AND INDUSTRIAL ASPECTS OF THE TUBERCULOSIS PROBLEM.

IN an interesting and instructive popular address entitled "The White Plague in its Social and Industrial Aspects," delivered by Sir Thomas Oliver at the opening of the Tuberculosis Exhibition at Middlesbrough on Dec. 1st, some useful information was collected and expressed in simple yet arresting language, together with thoughtful comments and suggestions. We have only space to refer briefly to some of the points discussed, but the whole address constituted an eloquent appeal to the public to assist in the campaign against tuberculous disease. It is first pointed out that the discovery of the tubercle bacillus has shown that, while the influence of heredity is not altogether to be ignored, at worst it only creates a predisposition, he claimed that this discovery has given hope, because it has opened the way to the study of the prophylaxis of infection by the two methods of preventing the bacillus from entering the body, and of improving the vitality of the body so as to resist infection. Sir Thomas Oliver, then quoted the returns for 1906 of the Registrar-General for the Dublin registration area, which show that in the professional and independent classes the tuberculosis death-rate was 0·63, in the middle-class 2·79, in the artisan and small shopkeeping class 3·54, and in the general service class 4·12 per 1000, and pointed out that these figures suggest that tuberculosis is associated with poverty. He maintained that it will not be far wrong to say that poverty and drink, accompanied by ignorance of the laws of hygiene, are largely responsible for the prevalence of pulmonary tuberculosis. He then considered the circumstances of daily life which may lead on to the way of infection by the tubercle bacillus, and emphasised the influence of badly lit, badly ventilated, dusty, and overheated rooms in favouring the spread of disease. The effects of smoke and dust, and of the dried expectoration of tuberculous patients, were also considered. He referred to some experiments carried out by Dr. Fritz Kristen, of Breslau, to determine the length of time tubercle bacilli remain alive in the dust which can float about in the air. This observer found the life of the tubercle bacillus to be very short, especially when the dust is exposed to daylight and sunlight. In street dust infected with tubercle bacilli the micro-organisms live from three to eight days, in cloth dust similarly infected they live from five to ten days, while in pulverised expectoration they are alive after four to seven days. On the other hand, allowance must be made for dust lying in cellar dwellings and badly lit houses, where the bacillus may retain its vitality for weeks or months. The importance of adequate diet and of good food was next emphasised by Sir Thomas Oliver, and he expressed the opinion that the high death-rate from pulmonary tuberculosis in France at the present time might be a distant but lingering back-wash of the wave of tuberculosis which passed over that country after the Franco-German war, caused by the deprivation of food and by the other rigours suffered during that time. The influence of alcohol in favouring infection by disease was next referred to, and then the rôle of milk from tuberculous cows in causing the disease especially in children was carefully explained. In connexion with preventive and curative procedures, Sir Thomas Oliver referred to compulsory notification as a wise provision. He emphasised the importance of better wages, better dwelling houses, and temperance, and urged that it is a wiser policy for a municipality to provide healthy dwellings for the poorer working classes, houses hygienically constructed, and provided with plenty of air-space and good water-supply, than to spend money upon sanatoriums and the maintenance of bereaved families. He strongly insisted that the milk-supply to our towns should be under the most careful municipal supervision. In connexion with a nasty habit indulged in by some persons—viz., moistening the fingers with saliva before turning over the pages of a book, Sir Thomas Oliver told an interesting story. It appears that in Michigan, a little while ago, the secretary of the Bureau of Health, struck by the large number of cases of pulmonary tuberculosis which had occurred in a particular office, had the leaves of the books examined, with the result that tubercle bacilli were found. The infection was proved to date from the time when a young clerk who had worked in the office, and was the subject of tuberculosis, had been in the habit of moistening his fingers with saliva before turning over the pages of the office books.

IT has been arranged to hold a discussion on Factors which Conduce to Success in the Treatment of Otogenic Brain Abscess at the meeting of the Otological Section of the Royal Society of Medicine on Friday, Jan. 19th, 1912, at 5 P.M., at 11, Chandos-street, London, W. The discussion will be introduced by Sir Victor Horsley and Mr. C. E. West, and the Otological Section are specially inviting members of other sections to take part in the discussion.

ANNUAL REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

II.

RESUMING consideration of some of the more important sections of Dr. A. Newsholme's report, to which allusion was made in our article of Nov. 25th,[1] we note that the discussion of several of the principal topics entered upon in his report for 1909–10 is renewed in the present volume.

Tuberculosis.

In the above-mentioned article we commented briefly on the medical officer's account of the diminished incidence of tuberculous disease in this country during the last 40 years and the consequent saving of human life. Passing on to consider the various means by which consumption is acquired, and the methods available for its prevention, he remarks that tubercle bacilli are present mainly in the immediate vicinity of acutely consumptive patients of careless habits. The recovery of the majority of persons only slightly attacked may be ascribed to the small dosage of infection they have received or to their high powers of resistance. This resistance varies considerably in amount, being reduced greatly by an attack of measles or of influenza, for example, and being increased by good

[1] THE LANCET, Nov. 25th, 1911, p. 1501.

housing and appropriate nourishment. Among populations living under nearly equal conditions of nutrition the mortality from tuberculosis is found to be highest in those most exposed to protracted infection and to dusty occupations; it follows, therefore, that the greatest possibilities of fruitful action by sanitary authorities lie in preventing such protracted exposures to infection and dust.

In the active campaign against tuberculosis very much depends on the prompt recognition and treatment of incipient cases, for by this means we attain the most hopeful prospect of recovery. Moreover, the recovery of each individual sufferer removes an active focus of infection before its discharge becomes massive and therefore seriously dangerous to others. Unfortunately, however, only a small proportion of patients have hitherto come under observation in their early stages. Discovery of tubercle bacilli in the sputum of a patient implies a stage of the disease which cannot be considered early, and it is in this stage that most of the sufferers first apply for relief. Accordingly, in devising measures for staying the ravages of this scourge it is desirable that the foregoing considerations should have due weight. In the present campaign it is gratifying to realise that much help is already being rendered by the medical staffs of many of the general hospitals and dispensaries, as well as by those of the special hospitals for consumption, who are affording facilities for the detection and treatment of early cases of the pulmonary form of the malady. With respect to the management of advanced cases of phthisis Dr. Newsholme declares that no other measure for diminishing the prevalence of the malady compares with the segregation of such cases under hygienic conditions.

Notification of Pulmonary Tuberculosis.

The medical officer next discusses the measures already authorised by the Local Government Board for securing notification to the sanitary authorities of the existence of individual cases of tuberculosis. Referring to the tuberculosis regulations of 1908, by which cases of consumption occurring in Poor-law practice are compulsorily notifiable to the medical officer of health, he speaks of many towns in which the regulations have been valuable in securing help and advice for cases profoundly needing it. The experience acquired having shown that no disability attached to the cases notified under these regulations a further step was taken by the Board in May of the present year by making all cases coming under the care of charitable hospitals and dispensaries compulsorily notifiable. Under the Order the patient is specially safeguarded against any official interference that may prejudice him in the earning of his livelihood. On the contrary there is abundant evidence, according to the report, of notification bringing help to the stricken patient that had previously been unattainable. After expressing a strong opinion as to the desirability that all cases of consumption should be reported (a procedure which is largely provided for in a recent Order[2]), Dr. Newsholme warns his readers that early notification will not be completely secured even under a general compulsory system in the absence of arrangements for examination of possible cases by skilled diagnosticians, and that such notification will only be entirely successful when the local authorities are willing to organise means for helping the notified patients.

Secondary Infections in Pulmonary Tuberculosis.

Appended to this report is a contribution to the study of secondary infection in pulmonary tuberculosis by Dr. A. C. Inman, of the Brompton Consumption Hospital. While his inquiry gives little hope of success in controlling secondary infections in cases of advanced tuberculosis, the outlook is more hopeful in afebrile cases. Dr. Inman concludes that in most cases of "open" pulmonary tuberculosis the tubercle bacillus is the predominating infective agent, and that the temperature-chart alone cannot determine the presence or the absence of a secondary infection.

Enteric Fever.

In the article in our issue of Nov. 25th statistical details were quoted from this report respecting the decreasing incidence of enteric fever in this country. The money value was also shown of the life-saving thereby effected in 1910 as compared with former years. Readers of the long series of reports of the Local Government Board will remember that from the first the medical department has been mindful of the duty of improving our scanty knowledge respecting the modes of propagation of this refractory disease. Until quite recently the cause of enteric fever prevalence has been commonly attributed to a specifically polluted water-supply. But in later years other causes, such as the conservancy systems of excrement disposal, the influence of flies and of carrier cases, infected ice-creams, have been investigated, whilst water-supplies have been improved, so that the relative proportion of enteric fever attributed to polluted drinking water has undergone considerable diminution. From an excellent report by the late Dr. H. T. Bulstrode[3] published in February last we learn that on account of their cheapness various kinds of molluscs, especially cockles and mussels, often insufficiently cooked, enter largely into the dietary of the poorer residents on the English and Welsh littoral. These molluscs being collected from sewage-polluted sites at the mouths of rivers have, in numerous instances, been the cause of illness by enteric fever and enteritis among the consumers. To the same effect the opinion of Dr. John C. Thresh, the county medical officer of Essex, is quoted, which shows that the remarkable reduction in enteric fever fatality in certain districts under his charge is due to the disuse during 1909–10 of contaminated shell-fish for food. He states that before this date the disease was generally most prevalent wherever most shell-fish was collected and eaten. It can hardly be accidental, remarks Dr. Thresh, that five of the districts formerly most severely affected with enteric fever are on the coast, or near the mouths of estuaries.

Reverting to our comments in THE LANCET of Nov. 25th respecting an exceptionally severe outbreak of enteric fever at Eccles, we gather that the circumstances were further investigated at the laboratories of Professor S. Delépine of the Owens College, at the instance of Dr. S. M. Copeman. After scrutiny and exclusion of the more usual sources of infection—viz., water, milk, fish, and other foodstuffs, as well as of the sewerage and drainage of the town—evidence rapidly accumulated incriminating ice-cream retailed by itinerant vendors as being the main vehicle for the conveyance of infection. The outbreak was sudden, and the majority of the patients were infected within a few days of each other. A definite history was obtained that within the incubation period polluted ice-cream had been consumed by more than 100 of the persons primarily attacked. Evidence was wanting as to how the ice-cream became infected; but the probability is that it was due to contamination of the ice-cream during manufacture by a person who had imperfectly recovered from fever, or who was a carrier of infection long after having suffered from the disease.

Cerebro-spinal Fever and Poliomyelitis.

For some years past a continued fever due to the presence of the meningococcus has been observed at considerable intervals in various parts of Europe and of America. This disease—namely, cerebro-spinal fever—has also occurred sporadically and in a number of limited outbreaks in certain parts of Great Britain during the last few years. Epidemic poliomyelitis has likewise been occasionally met with in this country in the course of the last few years. From a communication to the Académie de Médecine on May 23rd last by M. Arnold Netter, we learn that during the year 1910 epidemics of acute poliomyelitis appeared in many widely separated districts of France.[4] In August last we received information from a special correspondent of an outbreak of "spotted fever" in the area around Holsworthy in Devonshire. Later, in the same neighbourhood, cases were recorded of acute poliomyelitis which apparently led to difficulties of diagnosis. As the epidemic appeared to be spreading Dr. R. J. Reece, a medical inspector of the Local Government Board, was sent down and made investigations on the spot.[5]

Both these diseases appear to be definitely infectious. From the before-mentioned report to the Académie de Médecine we learn that during the epidemic of acute poliomyelitis which occurred in the departments of the Aube and Yonne instances were met with of direct infection, of familial contagion, and of infection after contact with a healthy individual from the affected area who served as an intermediary.

[2] THE LANCET, Nov. 25th, 1911, p. 1496.

[3] A review of this report appeared in THE LANCET of April 22nd, 1911 p. 1089.

[4] THE LANCET, Sept. 2nd, 1911, p. 709.

[5] THE LANCET, Sept. 16th, p. 843, and 23rd, p. 896.

Referring to cerebro-spinal fever Dr. Newsholme observes that attacks of that disease probably occur not infrequently undetected, because meningitis may be caused by infections other than the meningococcus, for instance, by the pneumococcus or by pyogenic organisms, and the symptoms caused by invasion of the meninges by these organisms simulate those of epidemic cerebro-spinal fever, due to the meningococcus.

(To be concluded.)

BRITISH MEDICAL BENEVOLENT FUND.

AT the November meeting of the committee 33 cases were considered and grants amounting to £318 made to 30 of the applicants. The current account is consequently overdrawn to the extent of no less than £457, and the committee urgently appeals for the help which is absolutely necessary unless next month's applications are to be passed over. Contributions may be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole-street, London, W. The following is an abstract of the cases relieved:—

Daughter, aged 31, of late M.R.C.S. Is a black-and-white artist, but has been unable to obtain work for several months, and is consequently in great distress. Health feeble. Mother a candidate for an Epsom pension. Voted £10.

Widow, aged 74, of L.R.C.P. Edin. Has supported herself since her husband's death 25 years ago by letting lodgings, but finds increasing difficulty in doing so. Only income 5s. a week, an old-age pension. Voted £12.

Daughter, aged 37, of late L.R.C.P. Edin. Used to live with her mother in Paris and maintain herself by giving English lessons, but has been in bad health for the last two years and is now quite penniless. Hopes to shortly obtain pupils or a situation. Voted £5.

Widow, aged 44, of M.R.C.S. No income, and dependent on the help given by a step-son and what can be earned by letting a room. Relieved three times, £36. Voted £12.

Widow, aged 81, of M.R.C.S. Has a small income, but is obliged to support her grown-up children, of whom three are deaf and dumb, and the fourth only able to do a little needlework. Relieved nine times, £60. Voted £5.

M.R.C.S., aged 70. Is quite incapacitated and dependent on his wife, whose income is very small. Relieved once, £10. Voted £5.

Widow, aged 69, of M.R.C.S. Has maintained herself for 30 years by letting lodgings at a watering-place, but is now becoming crippled by rheumatoid arthritis. Voted £12.

Daughter, aged 63, of L.R.C.P. Edin. Is matron at a small orphanage, but has been obliged for many years to devote most of her salary to assist an invalid mother, recently deceased, and now asks for a little help towards the funeral expenses. Voted £5.

Daughter, aged 37, of late M.R.C.S. Has held good engagements as governess and companion, but for the last few months has been unable to obtain a post, and has exhausted her small savings. Voted £5.

L.S.A., aged 66. Used to have a fair practice in a London suburb, but had a long illness with consequent pecuniary difficulties, and is now endeavouring to make a fresh connexion. Relieved once, £10. Voted £10.

L.R.C.P. Irel., aged 65. Practised for many years in London, but was obliged to give up two years ago on account of ill-health, and is now quite incapacitated. No income; wife supplements slight help from friends by letting lodgings. Relieved twice, £36 Voted £18.

Widow, aged 60, of L.R.C.P. Edin. Endeavours to support herself by nursing, but for the last few years has found it most difficult to get engagements, and is now practically dependent on a small temporary grant from a charitable society; health indifferent. Relieved once, £12. Voted £12.

Widow, aged 66, of M.R.C.S. Since husband's death has supported herself by acting as housekeeper, &c., but is now unable to obtain any post and quite dependent on this Fund and the uncertain help of friends. Relieved three times, £36. Voted £12.

L.R.C.P. Edin., aged 54. Has been incapacitated for several years by spastic paraplegia and is dependent on relations who can ill afford to help. Relieved seven times, £84. Voted £12.

Daughter, aged 64, of late M.R.C.S. Assisted her mother in keeping a boarding-house to maintain her father during a many years' illness and now helps two sisters who have a school but can give applicant no salary; health feeble. Relieved three times, £36. Voted £12.

Daughters, aged 61 and 52, of late M.R.C.S. Endeavour to support themselves by taking boarders and ask for help to tide over the winter. Relieved twice, £28. Voted £18.

Daughter, aged 63, of late M.R.C.S. Dependent on two brothers whose help is uncertain and is in very feeble health. Relieved five times, £60. Voted £12.

Widow, aged 70, of L.R.C.P. Edin. Only income an old-age pension of 5s. a week and is crippled by chronic rheumatism. Relieved four times, £48. Voted £12.

Daughter, aged 41, of late L.R.C.P. Edin. Endeavours to earn a living by nursing, but has had no case for some weeks and sees no prospect of one. Relieved seven times, £56. Voted £5.

Daughter, aged 56, of late M.R.C.S. Is subject to attacks of insanity and obliged to live very quietly in the country at the expense of three half-sisters who all earn their living. Relieved seven times, £66. Voted £5.

Widow, aged 75, of M.D. Lond., who was physician to a special hospital. Only income two small annuities which are insufficient for the little comforts necessitated by applicant's age and infirmities. Relieved six times, £36. Voted £5.

Daughter, aged 58, of late M.D. Lond. Has earned as much as possible since father's death many years ago by giving lessons in painting, &c., but is now in ill-health and quite dependent on a half-sister. Relieved 28 times, £208. Voted £10.

Daughter, aged 49, of late L.S.A. Is mentally deficient and entirely dependent on a sister, who is a nurse. Relieved six times, £68. Voted £12.

Daughters, aged 59 and 54, of late M.R.C.S. No income; small earnings from needlework and slight help from friends. Relieved seven times, £94. Voted £20.

Daughter, aged 54, of late M.R.C.S. No income and incapable of earning a living. Relieved four times, £37. Voted £15.

Daughter, aged 57, of late L.S.A. Is in feeble health and dependent on a sister-in-law, who is a widow. Relieved 11 times, £105. Voted £15.

Widow, aged 51, of L.S.A. Quite unprovided for at husband's death from cancer a few years ago and dependent on a son earning £1 a week; is very deaf and in feeble health. Relieved five times, £68. Voted £18.

Widow, aged 63, of M.R.C.S. Unprovided for at husband's death several years ago and entirely dependent on her children. Relieved 13 times, £166. Voted £2.

Widow, aged 56, of M.B. Glasg. Has maintained herself for several years by letting lodgings and by needlework, but is now frequently incapacitated by illness. Slight help from two daughters earning small weekly wages. Relieved three times, £42. Voted £12.

Widow, aged 54, of L.R.C.P. Edin. Practically no provision at husband's death a few years ago and endeavours to support herself by taking boarders. Relieved once, £10. Voted £10.

PUBLIC HEALTH IN INDIA.

(Concluded from p. 1577.)

II. HOSPITALS AND DISPENSARIES.

THE reports which we have received regarding hospitals and dispensaries refer, as we intimated in our last issue, to the triennial period, 1908–10.

Eastern Bengal and Assam.

Colonel R. Neil Campbell, I.M.S., speaks of the urgent need that exists for female medical aid. Thousands of poor women go without treatment from the feeling that it is improper to be treated by a male medical attendant, and because no women doctors or medical assistants are available. He considers that there should be at every district headquarters both a female sub-assistant surgeon, and, if possible, a midwife; at the larger subdivisional headquarters, one of the former; and at the smaller, one of the latter. He has drawn up a scheme for the gradual introduction of such a system in the Province out of public funds, but considers that it is an object which should strongly appeal to public charity. He draws attention to the urgent need of a new hospital at Dacca, now the provincial capital. Encouraging results are reported from the nastin treatment of leprosy, but the numbers are too small as yet to warrant any conclusion being drawn from them. The hypodermic injection of Forster's vaccine has been tried for dysentery in 177 cases with somewhat indefinite results. Intraperitoneal saline injections in collapsed cholera cases have been successful in 37 out of 41 instances.

United Provinces.

The government of these Provinces has made an important modification in hitherto existing rules by allowing district boards to open dispensaries where they are considered to be required without demanding that public funds necessary for the whole upkeep shall be provided. These dispensaries can now be started if private subscriptions are available to assist in their support, and grants in aid may now be made to existing private institutions of a desirable kind, which will thus be encouraged and strengthened by this official support. Great efforts were made to cope with the excessive prevalence of malaria, and travelling dispensaries were established in four of the most stricken districts. More than 31,000 patients were treated in this way. Free distribution of quinine was also carried out extensively. The excessive infant mortality has been inquired into systematically at Cawnpore by a lady doctor and two trained native female nurses; the chief cause was found to be tetanus, due to the unclean methods of local midwives; a scheme has been brought into operation for the training of these nurses. It is stated that the nastin treatment for leprosy has been tried, but without satisfactory results. It was expected that the new medical college at Lucknow would be opened in October of this year; training will be provided for the full medical curriculum, but it is not yet decided whether the course will be for four or for five years. Colonel C. C. Manifold, I.M.S., does not speak very hopefully of the preventive treatment of plague; he considers it useless to expect effective limitation

of rats where food supplies are accessible; inoculation, the one successful and scientific means of combating the disease, has not been accepted by the people; evacuation is not carried out for a long enough time, the people returning to their infected houses only to become victims of the disease; he has more hope from the travelling dispensaries. Some idea of the work done in the hospitals and dispensaries of this province may be gained from these figures: 4,543,746 cases were treated: 196,759 operations were performed.

Central Provinces and Berar.

Lieutenant-Colonel A. Buchanan in his report mentions a severe and unusual outbreak of guinea-worm disease in a village near Nagpur; over 100 persons were affected, all of whom drank water from one well, while the people who used the other four wells in the village were entirely free from the disease; a few persons drank water from the infected well, but filtered it through cloth; none of these were affected. The cyclops, which is the host of the guinea-worm (but which is not a small "insect" as described in the report), was removed from the water by straining through the cloth. Another interesting point is the mention of the occurrence of 25 cases of enteric fever at Chindwara among Indians with symptoms nearly the same as in Europeans; it is not stated to what native race these patients belonged.

Burma.

The principal item of interest in the report on Burma is the opening of the new general hospital at Rangoon, which, however, is not yet finished, though patients are now accommodated there. It is gratifying to note the large increase in women and female children treated; the numbers have risen from 8852 in 1908 to 14,586 in 1910. A considerable increase in syphilis admissions in Burma is noted, especially in Rangoon; venereal diseases are also prevalent at Mandalay; these points are deserving of the particular attention of the Government. Scientific work in the laboratory is carried on under difficulties in the climate of Rangoon; bacteriological investigations are, however, now conducted with success; one of considerable importance to the public health of the city was the detection of cases of glanders among men living in close contact with cab-horses.

III. JAILS.

These reports refer to the year 1910.

Bengal.

In this province a reduction in the average numbers in jail took place in 1910 from 15,065 to 13,163, due mainly to the good season of 1909–10, in which the petty thefts and minor offences of a population affected by scarcity and high prices were less numerous. Lieutenant-Colonel W. J. Buchanan, inspector of prisons, writes strongly against the present system of the employment of convicts as warders, many being appointed to positions of trust, even to be night guards, who were not eligible, but had to be employed owing to insufficiency of the regular warders. The question of alterations in the prison dietary is now under consideration, consequent on Major D. McCay's recent investigations.[1] The death-rate of prisoners was only 18·6 per 1000, the lowest yet recorded (except 17·5 in 1907). The improvement that has taken place has been extraordinary; in the quinquennium 1875–79 the death-rate was 65. The chief cause for this good result in 1910 was absence of overcrowding in the jails, owing to the prosperity of the province consequent on the excellent harvests. Dysentery was much less prevalent, also tuberculosis. Lieutenant-Colonel Buchanan alludes to the effects of the unrest in Bengal during the last few years; the prisoners are not so manageable as formerly, and the work of the jail officers has been rendered more difficult and harassing.

Eastern Bengal and Assam.

Lieutenant-Colonel B. J. Singh reports a steady increase in the number of prisoners since the formation of the new province in 1905, the daily average being now 8136. He complains that magistrates continue to commit juvenile offenders of 10 to 12 years of age to jail for short periods, in spite of recent orders by the Government. No suitable accommodation exists for these juveniles, and the risk of their contamination by the older criminals is very great; moreover, the jails were constantly overcrowded. The death-rate was 32·57 per 1000, a higher ratio than in any year of the decennium; dysentery and tubercle of the lungs were the chief causes of the increase. Lieutenant-Colonel Singh believes that there is a close connexion between the former disease and oral sepsis, and states that wherever medical officers had interested themselves in the proper care of the prisoners' gums and disinfection of their mouths the results were satisfactory. Forster's vaccine was not found to be effective as a dysentery prophylactic. Tubercle of the lungs was in many cases acquired before admission to jail, but the overcrowding and want of separate accommodation were largely responsible for its spread.

United Provinces.

In the United Provinces the jail death-rate was only 15·6 per 1000, compared with 23·7 in the previous year. This denotes a return to normal health after the famine and malarial epidemic of 1908–09. Dysentery was less frequent and fatal. Lieutenant-Colonel C. Mactaggart believes that this was because the prisoners were in better health and condition when received into jail. Tubercle of the lungs was also less severe; malaria was much less prevalent. It is interesting to learn that a female prisoner escaped from the prison at Benares by climbing over the wall, though she was 70 years of age. In her youth she had been an acrobat. But even so, the vigilance does not seem to have been up to the mark.

Central Provinces.

At Raipur jail dysentery caused 195 admissions and 49 deaths. Lieutenant-Colonel W. B. Lane states that the disease was introduced into the jail by a batch of prisoners from the Bastar State, and that it spread rapidly. At Nagpur jail, also, there was an epidemic of 90 cases with 11 deaths. In Lieutenant-Colonel Lane's opinion the disease is due to excess of food, the "unaccustomed plenty" of the jail.

Bombay.

In the Bombay Presidency the jail death-rate was 14·5 per 1000, a very satisfactory figure. No epidemic disease occurred of any importance.

Burma.

In the jails here the death-rate was only 11·98 per 1000, the lowest but one on record. An unfortunate misadventure occurred at one jail where a prisoner surreptitiously took a dose of concentrated solution of quinine, stated to have been at least 300 grains (!); he died in two hours.

IV. LUNATIC ASYLUMS.

In Bengal the rate of mortality among asylum patients was very low, being only 6·58 per cent. of the inmates, a lower figure than that obtaining in the county and borough asylums in England for 1909, which was 9·96. There were no deaths at all from fever. In Eastern Bengal and Assam the mortality rate was 11·81, tubercular disease having caused more than half the deaths at Tezpur Asylum; this was attributed to overcrowding, and the construction of a tubercle ward will be carried out during the current financial year. With the increased accommodation provided in the new hospital of the Punjab Asylum, by which all cases of tubercle, ankylostomiasis (from mud eating), and bowel affections are segregated, there has been considerable improvement in health. The majority of cases in the Indian asylums, of which reports have been received, were, as usual, cases of maniacal insanity.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns, having an estimated population of 16,157,797 persons in the middle of this year, 7472 births and 4869 deaths were registered during the week ending Dec. 2nd. The annual rate of mortality in these towns, which had risen from 13·1 to 14·2 in the three preceding weeks, further rose to 15·7 per 1000 in the week under notice. During the first nine weeks of the current quarter the mean annual rate of mortality in these towns averaged 14·2 per 1000, and was 0·3 per 1000 higher than that recorded in London during the same period. The annual death-rates in the 77 towns last week ranged from 7·5 in Walthamstow, 8·7 in Northampton, 10·2 in King's Norton, and 10·6 in Tynemouth to 21·4 in Sunderland, 21·6 in Wigan, 22·5

in Burnley, and 23·1 in Bootle. The 4869 deaths from all causes in the 77 towns were 481 in excess of the number in the previous week, and included 276 which were referred to the principal epidemic diseases, against numbers steadily declining from 2900 to 259 in the 14 preceding weeks. Of these 276 deaths, 68 resulted from infantile diarrhœa, 66 from measles, 57 from diphtheria, 38 from whooping-cough, 25 from scarlet fever, and 22 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases last week was equal to 0·9, against 0·9 and 0·8 per 1000 in the two preceding weeks. The deaths of infants under two years of age attributed to diarrhœal diseases, which had steadily declined from 2714 to 73 in the 14 preceding weeks, further fell to 68 last week, and included 29 in London and its suburban districts, 4 in Nottingham, and 3 each in Burnley, Leeds, and Sheffield. The deaths referred to measles, which had been 37, 51, and 44 in the three preceding weeks, rose to 66 last week; 11 deaths were recorded in Burnley, 9 in London, 8 in Nottingham, 5 in Norwich, and 4 in Manchester. The fatal cases of diphtheria, which had been 55, 64, and 61 in the three previous weeks, again declined to 57 last week, and of this number 15 were registered in London and its suburban districts, 5 in Liverpool, 4 in Manchester, and 3 each in Bristol, Stoke-on-Trent, Sheffield, and Cardiff. The deaths assigned to whooping-cough, which had increased from 16 to 32 in the four preceding weeks, further rose last week to 38, and included 7 in London, 5 in Birmingham, 5 in Sunderland, and 3 each in Walsall, Manchester, and Leeds. The 25 fatal cases of scarlet fever were equal to the average in the two previous weeks; 4 deaths occurred in Manchester, and 2 each in Stoke-on-Trent, Birmingham, Salford, Preston, Halifax, and Leeds. The deaths attributed to enteric fever, which had declined from 35 to 20 in the four preceding weeks, slightly rose to 22 last week, and of these 9 were recorded in London and its suburban districts and 3 in Bolton. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had been 2203, 2213, and 2166 at the close of the three preceding weeks, declined again to 2141 on Saturday last; 248 new cases of this disease were admitted to these hospitals during the week, against 292, 291, and 203 in the three preceding weeks. These hospitals also contained on Saturday last 1342 cases of diphtheria, 177 of whooping-cough, 86 of enteric fever, and 72 of measles, but not one of small-pox. The 1307 deaths from all causes in London last week were 161 in excess of the number recorded in the previous week, and included 297 which were referred to diseases of the respiratory system, against numbers rising from 170 to 243 in the four preceding weeks. The deaths attributed to different forms of violence in the 77 towns, which had been 167 and 158 in the two preceding weeks, rose to 188 last week, and 437 inquest cases were registered. The causes of 39, or 0·8 per cent., of the deaths registered in the 77 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, Stoke-on-Trent, and in 51 other smaller towns. The 39 uncertified causes of death in the week under notice included 8 in Liverpool, 6 in Sunderland, 5 in Birmingham, 3 in London, and 3 in Coventry.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 742 births and 589 deaths were registered during the week ending Dec. 2nd. The annual rate of mortality in these towns, which had been 18·6 and 16·7 in the two preceding weeks, rose to 18·0 per 1000 in the week under notice. During the first nine weeks of the current quarter the mean annual death-rate in these Scotch towns averaged 16·6, and was 2·4 per 1000 above the mean rate during the same period in the 77 large English towns. The annual death-rates in the several Scotch towns last week ranged from 14·5 and 14·9 in Perth and Leith to 18·8 in Glasgow and 20·8 in Aberdeen. The 589 deaths from all causes were 41 in excess of the number in the preceding week, and included 72 which were referred to the principal epidemic diseases, against 65 and 63 in the two previous weeks; of these 72 deaths, 31 resulted from measles, 16 from diarrhœal diseases, 15 from diphtheria, 6 from whooping-cough, 2 from scarlet fever, and 2 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 2·2 per 1000, and was 1·3 per 1000 above the mean rate from the same diseases in the 77 large English towns. The deaths referred to measles, which had been 13, 28, and 23 in the three preceding weeks, rose to 31 last week, and included 18 in Aberdeen and 11 in Glasgow. The deaths attributed to diarrhœal diseases, which had been 19 and 16 in the two previous weeks, were again 16 last week, and included 10 of infants under two years of age; 9 deaths were registered in Glasgow, 3 in Dundee, 2 in Edinburgh, and 2 in Paisley. The fatal cases of diphtheria, which had declined from 14 to 7 in the three preceding weeks, rose to 15 last week, and included 8 in Glasgow and 2 each in Edinburgh, Dundee, and Aberdeen. The 6 deaths assigned to whooping-cough, of which 3 were recorded in Glasgow, were equal to the average in the four preceding weeks. The 2 fatal cases of enteric fever, both of which occurred in Glasgow, were equal to the number in each of the two preceding weeks. The 2 deaths referred to scarlet fever were registered in Glasgow and Leith respectively. The deaths referred to diseases of the respiratory system, which had been 144 and 113 in the two preceding weeks, were again 113 last week, and were 44 below the number recorded in the corresponding week of last year. Of the 589 deaths from all causes in the Scotch towns last week, 161, or 27 per cent., were recorded in public institutions, and 16 were attributed to different forms of violence. The causes of 17, or 2·9 per cent., of the deaths in the eight towns in the week under notice were not certified or not specified; in the 77 large English towns the proportion of uncertified causes did not exceed 0·8 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 570 births and 403 deaths were registered during the week ending Dec. 2nd. The annual rate of mortality in these towns, which had been 19·0 and 18·0 in the two previous weeks, rose to 18·3 per 1000 in the week under notice. During the first nine weeks of the current quarter the mean annual death-rate in these Irish towns averaged 18·3 per 1000; in the 77 large English towns the mean annual death-rate during the same period did not exceed 14·2, while in the eight Scotch towns it was equal to 16·6 per 1000. The annual death-rate last week was equal to 21·6 in Dublin (against 15·1 in London), 13·6 in Belfast, 25·9 in Cork, 12·8 in Londonderry, 12·2 in Limerick, and 20·9 in Waterford; in the 16 smallest of these Irish towns the death-rate last week was equal to 19·8 per 1000. The 403 deaths from all causes were 7 in excess of the number in the previous week, and included 40 which were referred to the principal epidemic diseases, against 47 and 44 in the two preceding weeks; of these 40 deaths, 14 resulted from diarrhœal diseases, 11 from whooping-cough, 6 from diphtheria, 4 from measles, 3 from scarlet fever, 1 from enteric fever, and 1 from typhus, but not one from small-pox. These 40 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·8 per 1000; in the 77 English towns the mean annual death-rate from these diseases last week did not exceed 0·9 per 1000, while in the eight Scotch towns it was equal to 2·2. The deaths attributed to diarrhœal diseases, which had been 19 in each of the two preceding weeks, declined last week to 14, all of which related to children under 2 years of age; 6 deaths were recorded in Dublin, 2 in Belfast, and 2 in Waterford. The deaths referred to whooping-cough, which had increased from 1 to 11 in the four preceding weeks, were again 11 last week, and included 4 in Lurgan, 3 in Dublin, and 3 in Belfast. The fatal cases of diphtheria, which had been 12 and 2 in the two preceding weeks, again rose to 6 last week, of which 3 were registered in Dublin. The 4 deaths from measles were equal to the number in the previous week, and comprised 3 in Dublin and 1 in Cork. The 3 fatal cases of scarlet fever, which were 2 fewer than in the previous week, were registered in Dublin, Belfast, and Sligo respectively. The fatal cases of typhus and enteric fever were recorded in Dublin. The deaths referred to diseases of the respiratory system, which had been 75, 73, and 78 in the three preceding

weeks, were 77 last week. Of the 403 deaths from all causes in the Irish towns last week, 149, or 37 per cent., were recorded in public institutions, and 8 were attributed to different forms of violence. The causes of 12, or 3·0 per cent., of the deaths in the 22 towns in the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes last week did not exceed 0·8 per cent. in the 77 English towns, but was equal to 2·9 per cent. in the eight Scotch towns.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Staff-Surgeons: A. La T. Darley to the *Hazard*; and H. P. Turnbull to the *Vernon*, additional, for the *Furious*. Surgeons: R. A. Rankine and H. White to the *Victory*; W. L. Cowardin and Q. H. Richardson to the *Vivid*; L. A. Moncrieff and A. C. Paterson to the *Pembroke*, all additonal, for disposal; and G. D. Bateman to the *Victory*, additional, for disposal.

ROYAL ARMY MEDICAL CORPS.

Captain John W. West to be Major (dated Nov. 29th, 1911). Captain Edmund S. Worthington, M.V.O., is seconded for special extra-regimental employment (dated Sept. 29th, 1911).

The undermentioned officers are seconded for service under the Foreign Office:—Captain Ronald E. Todd (dated Nov. 1st, 1911). Lieutenant Campbell Robb (dated Nov. 14th, 1911). Lieutenant Robert Gale (dated Nov. 15th, 1911). Lieutenant Pierce M. J. Brett is confirmed in his rank.

Surgeon-General A. T. Sloggett, C.B., C.M.G., Principal Medical Officer of the Sixth (Poona) Division, Southern Army, has been selected for appointment as Principal Medical Officer of the Coronation Durbar at Delhi. Lieutenant-Colonel H. C. Thurston, C.M.G., on return from a tour of foreign service in Bermuda, has been posted to the Aldershot Command. Lieutenant-Colonel W. L. Grey, in charge of the Military Hospital at Winchester, has been detailed by the War Office for a tour of service in India. Lieutenant-Colonel R. Kirkpatrick, C.M.G., has taken up duty as Senior Medical Officer in Egypt. Lieutenant-Colonel N. C. Ferguson, C.M.G., has left Queen Alexandra's Military Hospital, London, and taken over charge of the Military Hospital at York. Lieutenant-Colonel J. S. Green, from Naini Tal, has been appointed to command the Station Hospital at Bangalore, in succession to Lieutenant-Colonel W. C. Beevor, C.M.G., tour expired. Lieutenant-Colonel H. J. Fletcher, commanding the Station Hospital at Sialkot, has received an extension of his command until May, 1913. Lieutenant-Colonel T. Daly has been appointed to command the Station Hospital at Peshawar for a period of three years. Lieutenant-Colonel A. L. F. Bate, commanding the Station Hospital at Kuldana, has been appointed Senior Medical Officer on board the troopship s.s. *Rewa* which left Karachi for Southampton on Dec. 9th. Major W. E. P. V. Marriott, at present serving in the Dublin District, has been posted to Mullingar with effect from Dec. 18th, on which date he will take over the charge of the Military Hospital at the latter station, in succession to Major C. S. Smith. Major R. Tilbury Brown, specialist sanitary officer to the Burma Division, has been permitted to extend his tour of service for one year. Major L. Way has been transferred from Golden Hill to Cosham. Major C. W. H. Whitestone, from Peshawar, has taken up duty at Cherat as Staff Officer for Medical Mobilisation Stores in the First (Peshawar) Division. Major H. S. Anderson, from Moore Park, has been posted to Buttevant Camp. Major F. W. Begbie, surgical specialist at Colchester, has taken over Medical Charge at Ipswich during the absence on leave of Lieutenant-Colonel H. L. Battersby. Major W. P. Gwynn, on return to India from leave, has taken up the appointment of Embarkation Medical Officer at Karachi for the current trooping season. Captain S. E. Lewis has been appointed to succeed Captain J. Tobin as Medical Officer in charge of the Military Families Hospital at Devonport. Captain F. J. Stuart has been transferred from the Eighth (Lucknow) Division to the Seventh (Meerut) Division for employment as Specialist in Dermatology and Venereal Diseases. Captain J. H. Brunskill has been selected for appointment as Clinical Pathologist at the Curragh. Captain S. Boylan-Smith has taken up duty at Belfast as Specialist Sanitary Officer. Captain R. P. Lewis has arrived home on leave of absence from South Africa. Captain P. G. Hyde, from Dublin, has embarked for a tour of service in Ceylon. Captain C. E. W. S. Fawcett, on return from Thayetmyo, Burma, and Captain M. J. Cromie, from Delhi, have been ordered to join for duty in Ireland, and on arrival will be posted to the Dublin District. Captain M. Keane, from Meerut, has been detailed for duty on board the troopship s.s. *Rewa* which left Karachi for Southampton on Dec. 9th. Captain A. E. B. Wood has embarked for a tour of service at Hong-Kong. Captain F. A. Stephens has been placed under orders for service in the Second (Rawal Pindi) Division of the Northern Army and will embark during the current trooping season. Captain J. H. Campbell, from Warrington, has joined at Bury. Captain H. H. A. Emerson, from Clonmel, has been appointed to Limerick. Captain D. S. B. Thomson has arrived home on leave of absence from Egypt. Captain H. Harding, from York, has taken up duty at Leicester. Captain M. F. Grant, from Aldershot, has joined the London District. Lieutenant J. R. Yourrell has embarked for a tour of service in Burma. Lieutenant O. W. McSheehy, from Taunton, has taken up duty in South Africa. Lieutenant C. M. Finny, from the Curragh, has been posted to the Dublin District. Lieutenant J. Gilmour has been transferred from Cardiff to Devonport. Lieutenant E. T. Gaunt, from Canterbury, has been appointed to the Military Hospital at Shorncliffe. Lieutenant G. H. Stack has been posted temporarily to the London District and attached to the Guards Depôt at Caterham pending embarkation.

INDIAN MEDICAL SERVICE.

The King has approved of the retirement of Lieutenant-Colonel Ernest Gerald Robert Whitcombe (dated Oct. 27th, 1911).

Lieutenant-Colonel T. W. Irvine has been appointed to officiate as Civil Surgeon at Peshawar. Lieutenant-Colonel P. J. Lumsden, Bengal Presidency, has received two months' extension of his leave of absence. Lieutenant-Colonel W. Vost, civil surgeon at Saharanpur, has been transferred for duty at Lucknow. The services of Lieutenant-Colonel J. Crimmin, V.C., C.I.E., have been replaced temporarily at the disposal of the Government of India by H.E. the Governor of Bombay. Major L. T. R. Hutchinson has been selected to hold charge of the office of Presidency Surgeon, Third District, Bombay, pending the arrival of Major A. W. Tuke. Major G. P. T. Groube has arrived home on leave of absence from India. Major V. H. Roberts has been appointed for duty under the administration of the Central Provinces as officiating Civil Surgeon at Seoni and to the Executive and Medical Charge of the Seoni District Jail. The Lieutenant-Governor of the Punjab has been pleased to appoint Captain D. H. F. Cowin to be a Civil Surgeon of the Second Class. The services of Captain B. B. Paymaster have been placed permanently at the disposal of the Government of Bombay. Captain H. Emslie-Smith, Bengal Presidency, has arrived home on leave of absence. Captain C. H. Reinhold has been permitted to extend his leave by the Secretary of State for India. Captain F. O. D. Fawcett and Captain G. M. Millar have embarked for India on termination of their leave of absence. H.E. the Governor of Bombay in Council has been pleased to appoint Captain A. J. V. Betts to be a Civil Surgeon of the Second Class and to officiate as Civil Surgeon at Nasik. The services of Captain G. J. Davys have been placed by the Home Department of the Government of India at the disposal of H.E. the Commander-in-Chief for military employment. Captain E. B. Munro has taken up duty under the Government of Eastern Bengal and Assam. Captain S. H. Lee Abbott has been transferred as Civil Surgeon to Dalhousie. Captain E. Bisset has taken up duty under the United Provinces Administration as medical officer in charge of plague prevention in the Meerut District. Captain W. Lapsley, civil surgeon of Azamgarh, has arrived home on one year and four months' leave of absence from India. The services of Captain V. B. Green-Armytage have been placed temporarily at the disposal of the Government of Eastern Bengal and Assam.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Harry Dudley Rollinson to be Lieutenant, on probation (dated Nov. 3rd, 1911).

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd East Anglian Field Ambulance, Royal Army Medical Corps: Lieutenant John K. Howlett resigns his commission (dated Dec. 2nd, 1911).

2nd East Lancashire Field Ambulance, Royal Army Medical Corps: Quartermaster and Honorary Lieutenant Sidney Pritchard is granted the honorary rank of Captain (dated May 28th, 1911).

2nd Lowland Field Ambulance, Royal Army Medical Corps: Lieutenant Alexander M. Watson to be Captain (dated Nov. 7th, 1911).

1st Northumbrian Field Ambulance, Royal Army Medical Corps: The undermentioned officers to be Captains: Lieutenant James W. Heslop (dated Oct. 25th, 1911), Lieutenant James P. Milne (dated Oct. 25th, 1911), Lieutenant William Simpson (dated Oct. 25th, 1911), and Lieutenant George H. Spencer (dated Nov. 2nd, 1911).

Attached to Units other than Medical Units.—Lieutenant John A. Preston to be Captain (dated June 8th, 1910). Lieutenant John J. Weaver resigns his commission (dated Dec. 2nd, 1911).

For Attachment to Units other than Medical Units.—John Crosthwaite Bridge to be Lieutenant (dated Oct. 14th, 1911).

ROYAL ARMY MEDICAL CORPS TRAINING IN IRELAND.

The General Officer Commanding-in-Chief in Ireland has arranged for a staff tour for the medical services to be held at Newcastle, county Down, from Dec. 11th to 14th. The directing staff will consist of Surgeon-General G. D. Bourke, C.B., K.H.P., principal medical officer, Irish Command; Brigadier-General F. W. N. McCracken, C.B., D.S.O., general staff, Irish Command; Colonel M. W. J. Edye, assistant director of supplies and transport, Irish Command; Colonel R. H. S. Sawyer, administrative medical officer of the Dublin District; Major C. Dalton, R.A.M.C, staff officer to the principal medical officer, Irish Command; Major D. J. Collins, R.A.M.C.; and Major A. Symons, general staff, Irish Command. The following Royal Army Medical Corps officers will take part in the tour: Lieutenant-Colonel J. H. Daly (Limerick), Lieutenant-Colonel O. R. A. Julian (Dublin), Major G. S. Crawford (Curragh), Major H. S. Anderson (Moor Park), Captain J. Dorgan (Cork), Captain J. H. Brunskill (Curragh), Captain W. D. C. Kelly (Dublin), Captain C. W. O'Brien (Kilbride), Captain S. B. Smith (Belfast), and Captain A. T. Frost (Dublin).

THE JAPANESE NAVAL MEDICAL DEPARTMENT IN THE RUSSO-JAPANESE WAR.

The fourth instalment of the translation of the Japanese Naval Medical report on the late war by Dr. Chemin, staff-surgeon in the French Navy, appears in the November number of the *Archives de Médecine et Pharmacie Navales* (O. Doin, Paris, 2 francs), and is concerned with the methods employed on board in the conveyance of the wounded to the dressing-stations. Most of them walked below by themselves; of the rest, by far the majority were men-handled, but the number carried down on stretchers increased as the war went on. The Japanese had had many of their ships built abroad, and with these had acquired examples of the stretchers of all nations. They examined them to find the most useful pattern, and ultimately concluded that, for their needs, the best was the one designed by their Surgeon-General Totsuka. This they call Renjo-Choka. It is essentially a double thickness of canvas, so sewn together as to leave narrow longitudinal channels, in which are inserted long, light slats of bamboo. Thus arranged, the apparatus can be folded round the wounded man, and the bamboo strips act conveniently as splints. Straps to secure him radiate from the perineum, and others tie the whole round his body. In the form it had reached at the end of the war the central strips behind his back were some six feet long to support his head as well as his body, the strips were omitted at the sides, and they were much shorter in front so as to clear his chin. The canvas extended above and below a little way, and through these extensions rope grummets were worked to give the bearers something to hold, to make carrying easier, and make lowering by a tackle possible. In the practice, which was assiduously carried out, the ambulance parties became very deft in the use of this appliance, which, as improved, gave every satisfaction. It was almost invariably used for carrying the wounded from the dressing station after their wounds were dressed, also for the conveyance of the dead; but the bearers were too anxious to get the wounded down to the doctors quickly to spare time in battle to use this stretcher for any but the serious cases.

Correspondence.

"Audi alteram partem."

THE NATIONAL INSURANCE BILL.

To the Editor of THE LANCET.

SIR,—At a meeting held to-day the following resolution was approved by every medical practitioner in Keighley and the immediate districts. I am, Sir, yours faithfully,

Keighley, Dec. 5th, 1911. JOHN B. BERRY, M.D. Edin.

That the National Insurance Bill as at present framed does not satisfactorily embody the reasonable demands of the medical profession as defined by the British Medical Association; that the scheme is unworkable, detrimental to the medical profession, and dangerous to the public health; therefore, in the event of the Bill becoming law in its present form, we medical practitioners in Keighley and district express our determination to refuse to undertake the duties which the Bill proposes to assign to us.

To the Editor of THE LANCET.

SIR,—Has not the time arrived when *per capita* contract practice should receive its true description—"*Speculation* in the care of the health and injuries of human beings"? What a truly magnificent gift to the nation is the sanction of Parliament to such a system! No end of arguments have come to you. From that of the gentleman who was anxious to split the "last straw" (a £20 bill) into so many portions as not to be felt, to those who find in the method freedom from all clerical work ("wait and see") and a chance of being paid something for nothing. Unfortunately for the former, if the German 40·2 per cent. invalidity incidence is correct and all the actuarial 6*s.* is for medical attendance, less than 18*s.* would be available for payment, £19 odd would remain the "last straw," and the poor doctor "the camel."

Is there a professional expert to be found who could correctly advise an outfitter the sum to quote to a newly married couple for the annual supply of their prospective family with clothing? All will agree they know of none; nor can one be found who would foretell with certainty the amount of sickness any given number of individuals must suffer in a year. The West Country expression sums it up: "'Tis all chance-work, isn't it?"

Surely, if we care nothing about future generations of medical men—and have we not a duty to them?—the effect *upon the patient* of any system adopted should be some concern of ours. I have had experience in England, Scotland, and Wales, and never found one who was getting his treatment on the *per capita* principle thoroughly satisfied; many much the reverse. Nor is the panel going to remove their objection; for I find that I annually attend some 150 patients who prefer to pay me whilst they have a panel of four to choose from—at the Chancellor's figure, too. Nobody disputes that half the cure is to impress the patient that you are going to do your best for him. The first essential to this is the belief that the service is willing.

The safeguards against over-attendance are for the framers of regulations to fix, not for the profession to worry out for them. What we must see to is that they are just, and that we are protected from being compelled to do unrewarded work. As an example: Some 600 or 700 people did not require a single night visit during a couple of months because they had to pay 2*s.* 6*d.* for it, but half a dozen of them when being attended gratuitously at the completion of the contract required two or three in a week. If the Insurance Committees are to be repaid the cost of excessive sickness, why not the medical attendant for excessive calls? Will "Old Moore" or will "Zadkiel" be the more likely expert to predict these periods of excessive sickness? Will an insufficient salary paid to the medical officer of health constitute "neglect to observe a public health precaution"?

Should we not insist that there is an actual "free choice of doctor" by securing the acceptance of the certificate of any duly qualified and registered medical man for payment of sickness and disablement benefit and not of those on the

panel only, otherwise a grave injustice will be inflicted on those who are willing to pay a medical attendant. We should also insist on absolute freedom as to what drugs and appliances may be prescribed; to secure continuance on the panel of those who give the best treatment available, as well as that nothing should be repeated without the written order of the prescriber. If the fee for attendance on cases where a midwife is in difficulty is to be payable by the local authority, should it not be something adequate, in view of the greater proportion of ordinary cases being attended by midwives?

A fund is suggested to recompense those who have been manufacturing the rope with which the Chancellor of the Exchequer is endeavouring to hang the profession! What of those who have, in loyalty to the best traditions of practice, refused *per capita* work?—I am, Sir, yours faithfully,

WILLIAM SPETTIGUE, M.B. Edin.

Wellington, Somerset, Dec. 4th, 1911.

To the Editor of THE LANCET.

SIR,—The position is so critical that the attitude of THE LANCET is of the greatest importance.

Many branches of the British Medical Association last week declined to consider the recommendations of the Council, and passed strongly-worded resolutions, to the effect that they would decline to act in any way under the Bill if it should be passed in its present form, and these resolutions were passed before it was known that the Council had sanctioned the acceptance by Mr. Smith Whitaker of an appointment as Insurance Commissioner.

Not one of the six points insisted upon by the representative meeting has been embodied in the Bill, unless it has been neutralised and rendered of no effect by other clauses; the profession will be face to face with health committees absolutely dominated by Friendly Societies; and the Insurance Commission (which has been given drastic powers without appeal) is composed of Friendly Society and Labour officials.

It is quite clear that if there were otherwise no objection to Mr. Smith Whitaker's acceptance of the appointment offered to him, there would be the objection that his appointment would be useless to the profession, as he would be outvoted perpetually; and even if he carried the Commission with him on some points, the points would be useless, in view of the fact that the requirements of the profession have not been accepted and embodied in the Bill.

In refusing to consider the recommendations of the Council a large number of members of the British Medical Association have practically censured the Council, and from all I hear the more recent action of the Council in approving of Mr. Smith Whitaker's appointment will be even more strongly condemned: if so, there will be no course open to the members of the Council other than to resign.

From the resolution already passed by the most important branches it is certain that the great majority of the profession will decline to act in any way under the Bill, unless at the last moment it is greatly modified by the Chancellor by amendments introduced during the passage of the Bill in the House of Lords. I venture to ask you to use your great influence to obtain such amendments, for as it stands the Bill, if passed, will be absolutely unworkable, and must be a failure. I am, Sir, yours faithfully,

S. Hampstead, Dec. 6th, 1911. ALBERT BENTHALL.

To the Editor of THE LANCET.

SIR,—Sir Alfred Pearce Gould states that there are no advocates for the system of State doctors and the system under which the State would undertake to pay the bills for medical attendance upon the insured. The former is advocated by many, and the latter by still more, and would be acceptable to every medical man, but not to any others of the tax-paying community.

Under a scheme of payment for work done the profession would, I believe, soon be reduced to an army of sixpenny doctors, worse off financially than under the present derided 4*s.* per annum inclusive-of-drugs contract rate. The medical man would receive no payment whatever from those who remained in good health, and but small ready cash fees for each attendance. There are other necessaries besides medical attendance, and a woman's 7*s.* 6*d.* benefit money would not prove sufficient to allow her to pay cash fees for the attention she needed in, say, a case of pneumonia, and the practitioner would very probably have to resume his wearisome task of booking, not the modest half-crown, but the still more modest sixpence.

Many years' experience of ordinary general and contract practice have taught me that the sick man very rarely requires any inducement to get well as quickly as possible, as the difference between his income when sick and when in good health generally provides sufficient stimulus, apart from the irksome rules and regulations to which he is required to submit when on his club.

The object of this Bill is "to provide for insurance against loss of health and for the prevention and cure of sickness, &c.," by enabling him to readily obtain all the medical help he requires in times of illness, in addition to a monetary consideration, small though the latter be.

If your readers will refer to page 1605 of THE LANCET of June 10th they will there find a workable scheme which, in a way, amounts to a combination of their present suggestions with that of ordinary contract practice, including in addition payment by the State for exceptional work, and where (1) the practitioner in attendance has a first call on the patient's sick benefit money to provide small (as good as cash) fees for emergency visits, night calls, and for the treatment of diseases due to misconduct; (2) the State would pay annually a small *per capita* rate, the minimum being 6*s.*, exclusive of drugs, &c., to provide the insured with ordinary domiciliary medical treatment; and (3) the State would act as the insurer, and pay extra for exceptional cases such as epileptics, major operations, consultations, anæsthetics, &c.

Herein the doctor, the patient, and the State are all safeguarded; the doctor against the main evils of contract practice, the patient against the possibility of being crippled by a big bill, whilst the State runs but very little risk of having to pay for an excessive amount of work done, inasmuch as the patient will not indulge in anæsthetics or operations if they can be avoided. Such a scheme would, I feel sure, solve our present difficulties, and there is nothing in the Bill to prevent any Local Insurance Committee giving it a trial. It is certain that Mr. Lloyd George is not fully convinced that £4,500,000 is inadequate to achieve his beneficent objects, and that he is prepared to find a greater amount than he had at first thought would prove sufficient. And unless the much-vaunted nobility of our profession is a misnomer it is our bounden duty to strain a point in order to help him all we reasonably can.

What do we find now? We find thousands of people suffering from all kinds of diseases who receive little or no medical attention, mainly owing to the bogey of payment for medical services: (*a*) the Poor-law doctor being inadequately paid limits his work as much as possible; (*b*) the club or contract practitioner likewise; (*c*) the hospital doctor is getting tired, as he gets no payment whatever from the ever-increasing numbers who claim his attention; (*d*) the private practitioner, having a ledger full of accounts of very little value, is often not desirous of increasing their number. A new social scheme is greatly needed, and the opportunity is at hand. Given adequate payment, with fair conditions of service, there should be a good time in store for every medical man. The consultants will still have their big fees, whilst the hospitals will have but little need to fear. If the Act needs amendment later in these respects, amendment will come.

The Bill will so soon become an Act that it is almost time that the discussion of terms should be taken up in earnest, as, though the Workmen's Compensation Acts provided the worker the wherewithal to pay for any treatment required, yet the profession was caught napping, and the lawyer got the cream, the doctor the skim milk, whilst the worker retained the cow.

Let us not be caught napping again.

I am, Sir, yours faithfully,

J. P. WALKER, M.D. Durh., D.P.H.,
Assistant County Medical Officer for Hants.

Winchester, Dec. 4th, 1911.

To the Editor of THE LANCET.

SIR,—Will you permit me, through the medium of your valuable paper, to express my strong disapproval of the action of the British Medical Association in advising their medical secretary, Mr. J. Smith Whitaker, to accept the post of Insurance Commissioner under the National Insurance Bill whilst the all too reasonable demands of the profession remain ungranted by the Government.

Surely it is time that the profession took some other steps

to defend its rights than those the British Medical Association has adopted. So far I cannot see that the British Medical Association has aided us or advanced our interests in any way, and I would appeal to you, Sir, to initiate some course that the profession may follow with better hope of success in opposing the degradation and robbery which this Bill threatens to impose on us. I am firmly convinced that the right course for us to adopt is to refuse absolutely and entirely to work under the Bill *at all*. Those who accept it and are willing to work under it will find themselves committed to the worst form of contract practice: they will be at the beck and call, night and day, of the insured persons; there can be no incentive to good work, and there will be every inducement to men to shirk in every way careful and painstaking work; and the complete demoralisation of that part of the profession which undertakes this work will inevitably result. If Mr. Lloyd George wishes to appoint salaried whole-time officers, let him do it, but let all self-respecting medical men refuse to coöperate with them or to assist them in any way, and I would urge that consultants refuse to meet them. In my opinion the Government are seeking to finance their unworkable Bill at our expense. Let us be careful that we do not help them.

I hope that all members of the British Medical Association will refuse any further contribution to the Defence Fund until the general opinion of the profession has been taken on the action of the Council. In conclusion I would protest most strongly against the squandering of the funds of the British Medical Association in the issuing of such circulars as that sent out respecting the appointment of Mr. Smith Whitaker on Saturday last, the 2nd inst. If the British Medical Association wished to notify the profession as to their action the notice in to-day's (the 5th inst.) issue of the morning papers would have sufficed, and would have cost the fund nothing. If the profession accepts and works under this Bill I am convinced that they will deeply regret it.

I am, Sir, yours faithfully,

REGINALD THORPE, M.R.C.S. Eng., L.R.C.P. Lond.

Tooting Common, S.W., Dec. 5th, 1911.

To the Editor of THE LANCET.

SIR,—It was apparent at first sight that a direct attack on our rights and privileges was contemplated by the Bill; it sets a disgracefully low pecuniary value upon medical services while claiming to be an improvement upon existing club systems; it imposes compulsory insurance and compulsory medical benefits upon classes who do not desire them, and endeavours to impress medical assistance at sweated and ignominious rates of remuneration; it cheapens medical labour in order that the Chancellor may be bolstered up in his preposterous electioneering catchword, "Ninepence for fourpence and free medical attendance thrown in!" Most unacceptable of all provisions, the insurance net was to gather in all whose incomes did not exceed £160 a year. At this point we reach the crucial pivot round which the whole measure revolves, and it is important to bear this in mind. Mr. Lloyd George persists in trying to insist on an insured income limit of £160 a year; the profession tell him firmly that the wage of any worker claiming inclusion in medical insurance must not, and as far as they are concerned will not, exceed £2 a week. Twenty thousand medical practitioners have pledged themselves not to accept service unless this and five other conditions laid down by a unanimous profession are incorporated in the measure before it becomes law. When the time comes, should the Bill now escape the fate of being dropped by its promoters, we have only to put our pledges into operation in order to make the Act the most ghastly administrative failure in the history of national Parliaments.

As things go now there is every reason to anticipate such an ending, for both general practitioners with an exclusively private practice and those who work only in club appointments are beginning to realise more fully to what an extent their practices would be detrimentally affected under the conditions of an income limit of £160 per annum. In the former case it means that in every household from which a certain medical income is derived every year there would in future be a percentage of compulsorily insured beneficiaries who must either henceforth be attended for the munificent fees of 4*s*. 6*d*. a year per head (about 1*d*. a week!) or else be handed over to an insurance or club doctor for attendance at the same rate. Of course, I recognise and concede the point that if the Local Insurance Committees are properly approached and bargained with later on the profession may obtain from their own gardeners, coachmen, or chauffeurs, elected through the Friendly Societies slightly better terms. But medical men have not yet, I hope, come to that. To pursue the argument, the total contributions of all a private practitioner's insurance beneficiaries, supposing for the moment we undertook that kind of work, would go a very short way towards recouping him on his ledger account for the pecuniary loss sustained through their conversion from private paying patients to State insured semi-paupers.

To put a concrete case. A man, his wife, and two young children would employ their usual medical attendant, while a couple of sons and a daughter earning money as clerks and a governess would come under the State scheme. The medical man would have to pry into their incomes, and then to raise the fine point whether their board and lodging, allowed perhaps by a wealthy father, was to count towards their annual earnings. If the family attendant elects to decline insurance work the clerks and the governess, along with the domestic servant, would be obliged to seek medical aid in a more remote and poorly populated neighbourhood, where in a crowded surgery they will patiently wait their turn cheek by jowl with the flea-bitten pauper and the Saturday-night alcoholic. To the private practitioner, therefore, the annual loss in income may amount to anything between a third and a half of gross receipts. There is no mention in the Bill about compensation for this loss, for which the Government would be clearly responsible, nor yet for the damage done to the saleable value of practices.

And the club doctor. What about him? He at the best is only promised a shuffle of the insured beneficiaries and a re-deal. He will gain some new, he will lose some old, ones, and every few months there will be another shuffle. The rate of pay will be very little better from the wealthy State than that which from force of competition, and by the exercise of his charity, he agrees at present to accept from the Friendly Societies and slate clubs. Should he, as is generally the case, be already overworked and sweated, with more patients than he can reasonably be expected to attend to properly, the Bill, even if it brings him an increase in numbers, will sweat him still more. Similarly his patients will suffer for the same reasons. Besides, the malingering loafer out of work will send for him on every possible and unreasonable excuse, and threaten to report him to his virtual masters on the Local Insurance Committees if he fails, through stress of work or any other reason, to respond promptly to the call. A more sharply defined line would be drawn between the club and private doctor. Nor is it necessary to do more than allude to the extra work, inconvenience, and discomfort for doctors and public alike which would inevitably attend a measure dependent for its operation upon a cumbersome and intricate system of committees, local committees, auxiliary committees, and subcommittees. They are all after-suggestions, small patches of sticking plaster intended to hide the gashes of trenchant criticisms to which the glaring incapacity displayed in the conception of the Bill invited attention. One thing is now quite certain: the profession will have none of it. Another thing is almost equally clear, which is that for some unknown or unpublished reason the mandate entrusted by the whole profession to the British Medical Association has not been as effectively put into operation as the individual members of the profession had a right to expect. It appeared to have been lost sight of by the Council of the Association that they sought and were freely accorded the moral support of the profession at large, irrespective of membership or non-membership, and that their mandate was briefly to amend the Bill in accordance with the generally expressed wishes of all, so as to conform with the cardinal points, the whole six points, and nothing but the six points, or else to drop all negotiation with the Bill, especially after the meeting of the representatives in London, to whom such a magnificent lead had been given by the united practitioners of Lancashire and Cheshire. Well, it is not too late even now, and if the blow delivered by the profession as represented by the British Medical Association has been weakly delivered, the Government have still to meet the resistance which will follow from the body of the profession. When the proper time comes and the Bill emerges

as law in its present form a real blow will assuredly be struck unless 20,000 men have pledged their word for nothing not to take service. Meanwhile, Sir, I feel that I am only voicing the sentiments of hundreds of fellow practitioners when I say that in view of recent events some more responsible leadership than that of the Council of the British Medical Association and one more in touch with the real wants of us all is required.

I am, Sir, yours faithfully,

Trinity-road, S.W., Dec. 5th, 1911. H. B. GREENE.

To the Editor of THE LANCET.

SIR,—I have read with interest the letters of Dr. B. Hall, and I am pleased that at last someone has ventilated the views of the rural practitioner, for hitherto the majority of your correspondents appear to have been resident in London or the suburbs. There appears to be no other way of making known the requirements of the rural practitioner except through the medium of the press, for the branch meetings of the British Medical Association are usually held in the large industrial towns, and the majority of country doctors, many of whom reside several miles from a railway station, have no opportunities for attending those meetings and ventilating their views; consequently the opinions expressed at those meetings are not fairly representative of the profession as a whole.

I hope to avoid the error which so many of your correspondents have committed, in writing for town and country doctors alike. I know very little of the working of a medical practice in a large industrial town. I am a country doctor, and I am absolutely convinced that the *per capita* system of payment is far and away the best and most lucrative in a rural district.

I am medical officer to three village clubs with a total membership of about 250, all adult males. A large majority of the members are agricultural labourers, probably the healthiest class of men in the community. I am paid 5*s*. per member per annum, and the amount of sickness is exceedingly small. On the other hand, about 45 of my clients in one village are members of the National Deposit Friendly Society, whose system (and rate) of payment "for work done" appears to be considered fair and reasonable by many of your correspondents. I find that during the last eight years I have received for those of the 45 who have required medical attendance the sum of £46 3*s*. 6*d*. If those 45 had been members of my clubs, paying me the *per capita* fee of 5*s*. per annum I should have received just £90 for them during the same period. I am also medical officer to a rural post-office, and I find that during the last five years I have received in capitation fees the sum of £12 10*s*. I have a record of the work done under that appointment, and I find that if I had been paid "for work done" at the National Deposit Friendly Society's rates I should have received just 19*s*. I am not appending my name to this letter in case the Postmaster-General should not consider my appointment worth continuing. I do not think that any post-office medical officer would willingly exchange the present system and rate of payment under those appointments for one of payment for work done.

I agree with Dr. Hall in thinking that those members of the profession who are crying down the *per capita* system of payment are without experience of it. I cannot say what the effect would be in the large industrial towns, but I am quite sure that in the rural districts where sickness is rare any substitution of a "payment for work done" system in place of the present *per capita* system would mean a serious falling off in income to a large number of country doctors.

There is another point wherein I consider that the British Medical Association is not reflecting the views of the country practitioners, and that is the "free choice of doctor" principle. Anyone who has bought a country practice knows that when an appointment held by a predecessor is not obtained by his successor one year's value of that appointment is deducted from the purchase money; therefore, when an appointment is obtained it is bought and becomes a vested interest. The "free choice of doctor" principle takes away that vested interest without any compensation whatever. I can quite imagine that if it had been Mr. Lloyd George who had introduced the "free choice of doctor" principle all those who have purchased club appointments would have been up in arms against his interference with vested interests, but as it is the British Medical Association instead of Mr. Lloyd George they appear to be silently acquiescing. Probably the principle will be beneficial to urban practitioners, but it appears to me that the country doctor is being sacrificed for the sake of his brethren in the industrial centres.—I am, Sir, yours faithfully,

Dec. 4th, 1911. RURAL PRACTITIONER.

To the Editor of THE LANCET.

SIR,—The sincere thanks of the medical practitioners of this country are due to you for the strong line which you have taken throughout the course of the debate in respect of the Insurance Bill as far as it affects, and will affect, the profession. You have continually and continuously made clear the evils of contract practice which would be crystallised under State authority if that Act comes into operation; and you have ever been on the side of the general practitioner, whose welfare and interests you have always supported in every possible way.

Owing to circumstances which all men of reason in the profession can appreciate, you have not sought to make capital out of the position for your journal; and your pen has been most carefully and wisely restrained, so as neither to engender nor to increase the grave feeling of mistrust which has arisen in respect of the negotiations which have been carried on by the constituted leaders of the profession, who were appointed to look after our best interests, but whose exertions and heavy expenditure of valuable time and money have proved, apparently, so ineffective. At this time of serious crisis I am sure you will use your best endeavours to assist in steadying the position, in preventing a *débâcle*, and in opposing any panicky action which might rend the Association and destroy its powers for good, which under wise direction it must possess.

I am, Sir, yours faithfully,

Dec. 5th, 1911. A. GEORGE BATEMAN.

*** For reasons explained in a leading article we did not publish last week many individual communications with regard to the National Insurance Bill. As correspondents have reproached us for "closing the correspondence," we must point out that no such silly action has been taken, while the views of many of those who wrote to us last week formed the backbone of the editorial comments. We take this opportunity of begging those who address us not to spoil good arguments by mere abuse of those with whom they do not agree.—ED. L.

THE ORIGIN OF CANCER AND THE ORIGIN OF LIFE.

To the Editor of THE LANCET.

SIR,—In his very interesting lectures on Unicellula Cancri Sir Henry Butlin has shown in a striking manner the parallelism that exists between the life and development of different varieties of cancer cells and that of many of the protozoa. He seeks to show, in fact, that "the carcinoma cell is an independent organism like many a protozoon," that it is "a complete animal organism in itself"; and he is now prepared to maintain this view, "not only for carcinoma, but for every variety of malignant disease."

Looking to the generally admitted facts that, as Dr. Bashford says, "cancer arises *de novo* in each individual attacked," and that it occurs "by a transmutation of functional somatic into cancerous cells," as was originally pointed out by Farmer, Walker, and Moore in a paper communicated to the Royal Society on Dec. 7th, 1905, together with the many analogies dwelt upon by Sir Henry Butlin, there seems very much to be said in favour of his view.

To some essential points in his statement, however, I must demur. While all students of cancer are now practically agreed that cancer cells are derived from the tissue cells of the part in which they take their origin, this cannot correctly be spoken of as a kind of process "which has never hitherto been imagined." It is exactly the kind of process known as "heterogenesis," many examples of which I have described and illustrated in my "Studies in Heterogenesis" (1903), and it is a process which has been defined as "the production from the substance of organisms or their germs of alien forms of life."[1] It is true the transmutation here does

[1] An illustrated description of one of the most notable examples observed by me may be seen in the Proceedings of the Royal Society, vol. B, 76 (1905), pp. 385-392.

not lead to the production from the altered tissue cells of what would be generally admitted to be independent living organisms; and certainly the process cannot possibly be cited as an illustration of "the origin of life." Life was already existent in the tissue cells—their mode of life has only been changed; a process allied to heterogenesis has occurred.

I cannot, therefore, agree with Sir Henry Butlin when he goes on to say: "The host in which it dwells has fashioned it out of its own tissues, and, to borrow the figurative language of Scripture, the Creator has breathed into it the breath of life. ..... After ages of past and present civilisation, during which searchers and philosophers have sought to explain the origin and nature of life, we have come no further than this."

The true origin of cancer, as I maintain, is related to heterogenesis, and not, as he thinks, to the still more mysterious problem to which he refers; nor can it fairly be said that in regard to the solution of this problem we have come no further than the establishment of this particular instance of heterogenesis.

Probably Sir Henry Butlin has never studied my little book entitled "The Origin of Life" (1911), where experiments are described in which multitudes of independent living organisms have been taken from tubes (previously sealed hermetically) containing certain saline fluids which had some months before been heated for periods varying from 5–20 minutes to temperatures ranging from 125–145° C., while most of the organisms that had been produced within the tubes were such (torulæ and micrococci) as are known to be killed by exposure in fluids to 60–70° C. for a few minutes. Such experiments surely take us much further towards the solution of "the great enigma" than does any mere proof of the heterogenetic origin of cancer cells—however much they may be shown to be related to many of the protozoa.

I am, Sir, yours faithfully,

H. CHARLTON BASTIAN.

The Athenæum, S.W., Dec. 2nd, 1911.

THE UNICELLULA CANCRI.

To the Editor of THE LANCET.

SIR,—Sir Henry Butlin has stated the case for the unicellula cancri with his wonted lucidity and force, but I venture to question whether he has reduced his thesis to the simplest terms. Is it not a fact that, viewed from the broad biological standpoint, all the cells of multicellular organisms (metazoa) are protozoa? Are not the aggregated cells constituting the metazoa and the segregated cells known as the protozoa all separate, individual animal organisms, bathed in a fluid from which they extract their oxygen and nutriment, and to which they yield their excreta? In the higher metazoa some of these cells—e.g., muscle cells and neurons—are highly specialised and have lost the power of multiplying: such never give rise to cancer cells. Others—e.g., epithelial, endothelial, and connective tissue cells—are less specialised and retain the power of multiplying: there is no doubt that it is from these that the cancer cells are derived. Do we, however, by labelling such cells "parasitic protozoa," "unicellulæ cancri," advance our knowledge?

The cancer cells are manifestly cells which have thrown off their allegiance to the body politic and become rebels. The whole problem of cancer is summed up in the question, What is the cause of this act of rebellion?

I am, Sir, yours faithfully,

Wimpole-street, W., Dec. 3rd, 1911. HARRY CAMPBELL.

PHYSICAL TRAINING IN SECONDARY SCHOOLS.

To the Editor of THE LANCET.

SIR,—I have read with great interest the article on "Physical Training in Secondary Schools," which appeared in your issue of Oct. 21st (p. 1150), and heartily endorse the contents thereof, especially the remark that "the gymnastic teacher should possess expert training and should be a member of the school staff." THE LANCET also points out that, whereas there are many expert lady teachers of Swedish gymnastics, there is a great dearth of expert male instructors. The reason for this state of affairs is that several excellent institutions exist for the teaching of lady students of gymnastics, but that there have hitherto been no similar institutions for male students. An inquiry into the arrangements for teaching gymnastics in other countries reveals the striking fact that the subject has been made a university one in a considerable number, and that special schools, controlled by the State, exist for the teaching of it. Let me quote some examples:—

Sweden.—The Royal Central Gymnastic Institute, founded at Stockholm in 1813, provides a course of study of three years' duration, which includes all the branches of Ling's system. The first two years are devoted to educational and military gymnastics, and the course of instruction includes anatomy (dissections are compulsory), applied anatomy of gymnastics, and physiology. The third year is devoted to medical gymnastics, some theoretical work in which has already been gone through in the second year. Examinations are held at regular intervals, and after passing the final examination the title of gymnastic director is conferred upon the candidate. The institute is under medical supervision, and the chief teachers have the title of Professor and rank as such.

Belgium.—The Institute Supérieur d'Éducation Physique attached to the University of Ghent was duly opened in 1908. After three years' training in physical education the candidate receives the title of Licentiate in the Science of Physical Education. Later on, after further examination and the presentation of a thesis which the licentiate must defend, he may obtain the title of Doctorate in the Science of Physical Education. The syllabus of the course seems to show that it is very complete.

In Austria there are State institutions in Vienna, Prague, and Gratz. Similar institutions are to be found also in Bavaria, Prussia, Saxony, and Norway. I see, also, that physical education is included in the curriculum of the University of Wisconsin. In Denmark the subject of gymnastics has quite recently been made an optional subject for the degree of B.A., B.Sc., and diplomé as school teacher.

In England gymnastics is, I regret to say, neither a university subject nor one which interests the medical profession as a whole. Indeed, I have no hesitation in saying that a medical man who opened a gymnasium for educational gymnastics would be shunned by his colleagues. Even the medical supervision of school gymnastics is almost an unknown factor in this country. This is not as it should be, and I consider that THE LANCET exactly states the case when it says that there should be a close coöperation between the medical officer and the gymnasium instructor. The fact cannot be denied that physical education largely enters into the subjects of hygiene and prevention of disease, and that overdoing or misuse of it leads to pathological conditions, especially in school children. Under these circumstances I feel that many will agree with me when I suggest that physical education be made one of the subjects of the ordinary medical curriculum.

The state of affairs at present is that gymnastic classes are held in the vast majority of the schools by people who are not competent to take them, and as matters stand now children with adenoids, with spinal curvatures, with weak chests are all performing the same gymnastic exercises together with healthy children, and they are doing so under the direction and control of a teacher who is incapable of judging whether he is doing good or harm thereby. Outside schools we have an equally deplorable state of affairs in many directions. The advertising quack who does a large and flourishing trade in so-called scientific gymnastics, with or without some special apparatus, and who boasts of self-arrogated invention and discovery, need only be mentioned.

The only way to improve matters is for the medical profession to take them into their own hands, for until they do so no change can be effected, and I sincerely hope this will be done ere long. In connexion with this, however, I should like to point out that an institute for teaching educational gymnastics will be open in this city in Marylebone in the immediate future. The object of the institute is to give thorough instruction, theoretical and practical, in the science of physical education on the basis of the Swedish system of gymnastics. The course of training will follow as closely as possible the lines upon which the Royal Central Institute at Stockholm is working, with such modifications as occasion requires. The syllabus of the Board of Education will be thoroughly studied and the requirements of the Board will be

met. Anatomy, physiology, theory of movement, hygiene, &c., will be included in the syllabus. The practice of gymnastics will be learnt and taught by students, for which latter purpose classes of school children will be available. The course of training will be of two years' duration, but is so arranged that the first year will form a complete course by itself, fitting the student for posts in elementary schools. The second year's course will enable the graduates to take full charge of any school of whatever standing. A special feature of the institute will be that facilities will be afforded to medical men to gain information and to critically observe the work done.—I am, Sir, yours faithfully,

EDGAR F. CYRIAX, M.D. Edin.

Craven-hill, W., Dec. 2nd, 1911.

THE PRESCRIPTION OF TUBERCULIN.

To the Editor of THE LANCET.

SIR,—In the courteous review of our work "Diseases of the Lungs," which appeared in THE LANCET of Nov. 25th, the important question is raised as to whether tuberculin should be prescribed in fractions of a cubic centimetre or milligramme. Before advocating the prescription and dispensing of the remedy in cubic centimetres we went carefully into the matter with Messrs. Squire and came to the conclusion that for accuracy and facility of dispensing the volumetric measurements were the best.

We beg to submit the following memorandum which we have received from Mr. P. W. Squire on the subject.

We are, Sir, yours faithfully,

R. DOUGLAS POWELL.
P. HORTON-SMITH HARTLEY.

London, Dec. 4th, 1911.

[ENCLOSURE.]

The writer of the review in THE LANCET of Nov. 25th, 1911, is evidently under the impression that he would be obtaining the same amount of solid substance whether he ordered a fraction of 1 gramme or of 1 cubic centimetre of tuberculin, but, of course, this is not so, because 1 cubic centimetre of the bacillary emulsion, for example, weighs 1·114 grammes, and this difference will have to be allowed for in each individual dose of dilution if it were ordered by weight. This introduces an unnecessary factor and an altogether needless amount of trouble. So far from simplifying matters prescribing "by weight" would be introducing complications. When prescribing tuberculin by measure (in cubic centimetres) it diminishes any possibility of a misunderstanding as to whether the figures relate to the liquid itself or to the solid substance it contains. It is, for instance, a simple matter to recollect that 1 cubic centimetre of emulsion represents 5 milligrammes of solid matter, but not so easy to recollect that 1·114 grammes of the liquid is equivalent to the 5 milligrammes. The fact that the emulsion is standardised to 1 cubic centimetre indicates that it is intended to be prescribed "by measure" and not "by weight." It is also much more convenient to work a fluid "by measure" than "by weight."

P. W. SQUIRE.

THE VALUE OF THE ALBUMIN REACTION IN TUBERCULOUS SPUTUM.

To the Editor of THE LANCET.

SIR,—The recent announcement of Lesieur and Prirey[1] as to the presence of albumin in tuberculous sputum seemed to afford a valuable and simple aid to the diagnosis of phthisis. Being temporarily in charge of the Birmingham Municipal Sanatorium at Yardley-road at the time of the article in THE LANCET[2] I took advantage of the opportunity to test the value of the reaction. The author's technique was adhered to throughout, and in the final stages nitric acid was used in preference to the heat method as being more delicate and accurate.

I was able to examine the sputum of 55 patients, of whom 39 had tubercle bacilli present and so were definitely tuberculous. Of these 39 albumin was present in 21, or 53·8 per cent., and absent in 18, or 46·2 per cent., so that the test appears to have no diagnostic value. No very extended conclusions can be drawn from such a small number of cases, but there appears to be a greater likelihood of the reaction being given if tubercle bacilli are present in the sputum, for of the remaining 16 cases which did not present tubercle bacilli, yet which otherwise showed all the signs of phthisis, and were, I think, undoubtedly tuberculous, only 4 gave the albumin reaction and 12 were negative.

I am indebted to my friend, Dr. W. H. Wynn, the visiting physician, not only for permission to publish this, but also for the interest he took in the matter, and to Miss D. Dawson for her assistance in the laboratory.

I am, Sir, yours faithfully,

H. S. GETTINGS, L.R.C.P. & S. Edin., L.F.P.S. Glasg., D P.H. Birm.,
Assistant Medical Officer, Portsmouth Municipal Tuberculin Dispensary.

Dec. 1st, 1911.

A SPHYGMOGRAPHIC METHOD FOR THE ESTIMATION OF SYSTOLIC AND DIASTOLIC BLOOD PRESSURE.

To the Editor of THE LANCET.

SIR,—Mr. S. G. Longworth correctly remarks that in current descriptions of the Korotkoff method for the determination of the diastolic blood pressure this is read off "at the point at which a distinct change in the intensity of the sound occurs." This alteration in intensity, pitch, and duration of the sound may be phonetically represented by *swish* to *dup*; the sound *dup* gradually increases to a maximum and then dies away as the air escapes.

The maximum intensity of the sound is taken as representing the diastolic pressure, but it is not always easy to determine this point, and different observers when examining the same patient frequently give different results, and, moreover, the sound not seldom continues equally loud over considerable differences in pressure.

I take the disappearance of the sound as the standard because the event can be certainly and readily determined, and thus has value for comparative observations on the same case. The reading so obtained is perhaps lower than the true diastolic pressure, but the difference would appear to be small. "Miss Allen and Mr. Engle, in the study of the blood pressures of 35 patients in the Johns Hopkins Hospital, found that the readings by the Korotkoff method never differed more than 2–5 mm. from control determinations made at the same time with the Erlanger apparatus, though they took the minimal pressure at the point at which the second sound absolutely disappeared."[1]

I am, Sir, yours faithfully,

J. DAVENPORT WINDLE.

Southall, W., Dec. 4th, 1911.

SUTURE OF THE ABDOMINAL WALL WITHOUT BURIED SUTURES.

To the Editor of THE LANCET.

SIR,—In April, 1906, I described in THE LANCET[2] a double-loop suture which I have reason to believe has proved useful. Recently I have experimented with another form of suture which fulfils similar conditions and possibly has some advantages. The double-loop suture had been used by several surgeons before my description of it, and this may be the case with regard to the method I wish to describe.

The advantage of the new method is that, having a single loop, it is more easily removed, and also that it draws the deep parts together with more lateral strain, thus approximating to the action of a buried suture.

A curved needle armed with silkworm gut is passed from without at some distance from the edge of the incision and through a layer of deep tissues on the opposite side; it is then repassed through the skin somewhat in front of the first puncture. The same process is repeated from the other side, the loops being interlocked. They may be tied independently, or one end may be left long and tied to the corresponding long end of the other loop.

These sutures act as "tension sutures," and a continuous horsehair is all that is required to complete the union. In removing the sutures it is best to cut both sides, otherwise the interlocking makes removal more difficult.

I am, Sir, yours faithfully

J. B. PIKE, M.R.C.S. Eng.,
Honorary Surgeon to the Loughborough Hospital.

Loughborough.

[1] Hirschfelder: Diseases of the Heart and Aorta.
[2] THE LANCET, April 7th, 1906, p. 967.

MUNICIPAL HONOURS.—Mr. R. J. Ryle, M.D. Oxon., M.R.C.S. Eng., J.P., was on Nov. 22nd elected a member of the Brighton town council by a majority of 190 votes over his opponent.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Royal Infirmary and the Insurance Bill.

THE chairman of the board of management has sent a letter to all Members of Parliament for the district from which the infirmary patients are drawn stating that in the opinion of the board the Insurance Bill, as it now stands, will seriously affect the financial position of voluntary hospitals, impairing their efficiency and capacity for good, so that insured persons will run grave risks of being deprived of care and attention in cases of serious illness, and urging that hospital benefit as well as medical and sanatorium benefits should be provided by the Bill.

Jewish Kitchen in Royal Infirmary.

After a good deal of correspondence and discussion the authorities have decided to establish a separate Jewish kitchen, conditional upon the Jewish community defraying the expenses, providing the utensils, and employing the cook.

The Cancer Hospital and the Causes of Cancer.

The annual meeting of the Christie (Cancer) Hospital was held on Nov. 27th. This institution, besides offering treatment and providing a home for acute cases, undertakes the study of the disease. The committee, in coöperation with the Pilkington trustees, has this year appointed Dr. C. Powell White as pathologist. During the year there were 101 in-patients and 41 out-patients. The subscriptions fell from £424 to £377. Many patients are admitted in a late stage of the disease for the alleviation of their suffering during the close of their lives. The death-rate from cancer seemed to be increasing. In Manchester last year 1 in every 17 deaths in the city was due to cancer, the total being 660 out of 11,374 deaths. For the first time in the history of the hospital during its 19 years' existence the number of men patients has been nearly as large as that of women. Dr. Powell White dwelt on the need for a fully equipped laboratory, as well as for an inquiry into the habits, occupations, and hygienic surroundings of the patients. He pointed out that the parts of the body most liable to disease varied in different countries, and in many cases the variations could be traced to specific habits. In Europe and in all temperate countries cancer of the stomach was the commonest form. In Travancore, in the south of India, where the natives chewed the betel-nut, the cancer most commonly affected the mouth; while in Cashmir, in the north of India, where the natives carried charcoal stoves under their clothes to keep them warm, the parts of the body that came in contact with the stoves were most affected.

A Great Water Scheme.

The Ashton, Stalybridge, Dukinfield, and Mossley district waterworks committee has undertaken a tremendous piece of work in relation to their water-supply. Over £1,000,000 have been spent in connexion with the Chew Valley scheme, which will be completed a few months hence, affording provision of water for many generations to come, with no risk of shortage of water even in the longest drought.

Sewage Purification: £40,000,000 Wasted Annually.

Dr. Grossmann, in a paper read on Dec. 1st before the Manchester Section of the Chemical Industry, stated that if all the valuable manurial constituents which are present in sewage could be utilised on the land they would represent a value of somewhere about £40,000,000 annually. The water-carriage system at present in use was the most wasteful system on economic grounds, but it was recognised that its advantages from a hygienic point of view should be such as to outweigh commercial considerations. The sewage at the sewage works, consisting of a liquid and solid part, underwent further purification; the liquid part ultimately found its way into the rivers and sea, and if the purification was thoroughly carried out would fulfil all anticipations with regard to the public health. The disposal of the solid part, however, was still a danger to the community. If the "sludge" was carried out to the sea there was danger of infection to sea life, such as oysters. Moreover, part of it might be washed back to places on the coast, as had actually occurred at several seaside places. If dumped on the ground it created a nuisance, and if used on land for farming purposes there was danger of infectious diseases being communicated to cattle and human beings from grass and grass crops on such land. The value of sewage sludge, calculated on the dry substance contained in it, was only 10*s.* a ton, and it did not pay the farmers to use it, except those in close vicinity to the works, on account of the cost of carriage. Nor could it be profitably used as a producer of illuminating gas. Until, therefore, the disposal of sludge was effected by sound hygienic methods there was still danger to the community. No process for the disposal of sewage sludge could be considered satisfactory which did not return the manurial constituents contained in it to the soil in a thoroughly sterilised condition, and sludge could never become a valuable manure unless it was previously freed from the greasy matters arising from soapsuds and other fatty substances which in the sewers became mixed with the sludge and prevented its manurial constituents from being assimilated by the plants.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Public Health and Infant Mortality.

THE second lecture of a series on the Civic Life of the City" was given at the Friends' meeting-house by Dr. E. W. Hope, the medical officer of health, on Dec. 3rd, the subject of the lecture being "The Public Health." He showed that the rate of mortality of all great centres of population was largely contributed to by infant mortality, and any causes, therefore, which directly or indirectly lessened the amount of attention paid to infants added to that mortality. Privation, for example, which deprived the nursing mother of food, immediately affected the infant, who then readily fell a victim to adverse circumstances. The subject had been recognised as one of such vital importance that in Liverpool and other places the health committees had established special committees whose sole function was the preservation of infant life. Dr. Hope then drew attention to two important Acts of Parliament specially designed to safeguard infants—namely, the Midwives Act of 1902, which provided for the training, regulation, and supervision of midwives, and the Notification of Births Act, which enabled visits to be paid to houses where such visits were needed. Various structural alterations and improvements relating to housing, hospitals, &c., were then described by Dr. Hope, who also dealt in an interesting manner with the water-supply of the city, maintaining that it was the best possible. The lecture was illustrated by means of lantern slides and was cordially appreciated.

Wireless Telegraphy at the University of Liverpool.

Through the generosity of Sir William Hartley, the University will shortly be able to receive messages by wireless telegraphy. Sir William Hartley has generously undertaken to defray the cost of a complete installation at the University. Professor Marchant, the head of the department of electrical engineering at the University, will control the installation. Sir William Hartley is to be congratulated upon his public spirit and great generosity, which will prove of incalculable advantage to teaching and research at the University.

Liverpool School of Tropical Medicine and Yellow Fever.

When the late Sir Rubert Boyce collected funds to form the Yellow Fever Bureau at the Liverpool School of Tropical Medicine he contemplated the despatch of an expedition to some country infested with yellow fever to make further research into its cause and treatment. In pursuance of this object the school has now decided to send out Dr. Harold Seidelin, scientific secretary of the bureau, to conduct some new and important researches into the disease, in Yucatan, Mexico. Dr. Seidelin leaves for New York by the *Mauretania* on Saturday, Dec. 9th.

Garston's New Accident Hospital.

The finance committee of the Liverpool city council has decided to offer the executive committee of the proposed new accident hospital at Garston £7500 towards the erection of a new hospital, and this proposal was put before a meeting of the executive committee held on Nov. 29th. Some time ago when the matter was first mentioned, the Liverpool city council offered £5000 towards the new hospital; but

this was not considered sufficient to free Liverpool from its obligation, which was incurred at the time of the incorporation of Garston, and a petition was extensively signed by the residents of Garston in support of Councillor Rawlinson's amendment that £10,000 should be granted by the city council. This was defeated by the council, and the matter has since been brought up, as under the will of the late Sir Alfred Jones the committee should receive £10,000 towards the building and maintenance of a new hospital, which is urgently needed. The committee decided to accept the offer of £7500, if the city council sanctioned the proposal of its finance committee.

Bootle Borough Hospital and National Insurance Bill.

At a meeting of the committee of the Bootle Borough Hospital the following resolution was carried unanimously:—

That the general committee of the Bootle Borough Hospital is unanimously of the opinion that the National Insurance Bill is incomplete unless it provides for the hospital treatment which insured persons must have if their medical needs are to be covered by the Bill.

In passing the resolution the committee is of the opinion that under the operation of the Bill in its present form the hospital will suffer loss of annual income to the extent of about £1000, and will still be called upon to provide for the same number of in-patients, with a very slightly reduced aggregate of out-patients, out of its considerably reduced income. The committee desires the recognition of voluntary hospitals which are largely dependent for their incomes on workmen's contributions, and who obtain treatment for themselves and families in time of need.

Dec. 4th

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

New Lectureship for the University of Aberdeen.

THE late Mr. John Thomson, printer, of the Aberdeen University Press, Limited, in his will instructs his trustees on the death of his wife to pay to the University Court of Aberdeen the sum of £2000 to found and maintain a lectureship on "The Structure and Functions of the Human Body," in order "to afford information to young persons as to the due care of the body in early life with a view to its healthy development and the prevention of its abuse by intemperance, &c." The lectureship is founded in memory of the founder's son, the late John Farquhar Thomson, M.A., who was first bursar in his year in arts at the University of Aberdeen. The University Court is instructed that a member of the University teaching staff shall yearly be appointed by them to hold the lectureship, the lectures to be delivered during the winter session of each year and to be of such number as the University Court, on the recommendation of the Senatus, shall fix when making the annual appointment. The lecturer is to be paid the full revenue of the said £2000, the lectures are to be delivered in the University Buildings at Marischal College, and are to be open, without fee, to the public.

Alleged Premature Dismissal from Hospital.

In the Dundee Sheriff Court on Nov. 27th, Sheriff Neish issued his interlocutor in an important action brought against the Dundee town council. The pursuer, a cabinet-maker, as an individual and as tutor and administrator-in-law to his children, sued the town council for £60 as damages by reason of their having, he alleged, discharged his daughter from the King's Cross fever hospital, Dundee, before the fever, from which she was suffering, had run its course. In consequence of her alleged contagious and dangerous condition three of the pursuer's children shortly afterwards took infection from her and suffered from illness. The town council denied negligence and pleaded that the action was irrelevant and incompetent. The sheriff-substitute found that the pursuer's averments were not relevant and dismissed the action, finding the pursuer liable in expenses. In a note, his lordship said that pursuer did not aver that the medical officer was defenders' servant. All he said was that the defenders were responsible for their medical officer. He did not think it could be maintained that the medical officer was the servant of defenders. His appointment was regulated by the Public Health (Scotland) Act, 1910. His duties were not prescribed by defenders, but only with the approval of the Local Government Board, and he could not be removed from office except by, or with the sanction of, that Board. In the sheriff's opinion the defenders had performed the duty incumbent on them in a question such as was raised in the case at issue. They had a competent and qualified man as medical officer, and the Local Government authority could control the medical officer's administration. The result was that pursuer had not set forth any relevant grounds for his claim, and dismissal of the action appeared to be the appropriate consequence.

Dec. 5th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Council of the British Medical Association and the Insurance Bill.

THE action of the Council of the British Medical Association in advising its medical secretary, Mr. J. Smith Whitaker, to accept the deputy chairmanship of the Insurance Commission is giving rise to comment in Irish medical circles. It is thought inconsistent for the Council, while stating that the "Insurance Bill, if it becomes law in its present shape, is fraught with danger to the public and to the medical profession," to recommend its chief executive officer to accept office for the purpose of administering the Bill. The Council is handing over its chief of staff to the opposition. Already the profession in Ireland was losing confidence in the British Medical Association, and this action of the Council is likely still further to diminish its confidence. It is felt that while the Council had no right to control Mr. Smith Whitaker's actions, it should not have seemingly recommended his appointment. In view of its action it is difficult for the Council at a later date, if deemed necessary, to advise the profession not to accept employment under the Bill. On the other hand, some few of the profession consider that under all the circumstances it was right to accept the offer, as it indicated that Mr. Lloyd George was holding out an olive branch to the medical profession. Looking at the situation calmly and dispassionately, the moderate men in the profession believe that the Council of the British Medical Association would have shown more diplomatic, if not indeed more legal, acumen had they told their official that he must accept or decline the position solely as a private individual and without seeking their approval; or, better still, had they withheld their own views until they had consulted the rank and file of their members through the Representative Body. To say that there was no time to do this is no adequate excuse, for the members of the Representative Body could have been summoned for Dec. 6th, just as easily as the Council was, and as they had been consulted in other matters in the previous negotiations why should they not have been in this? There is great fear that the action of the Council may injure the movement for welding the medical profession together. So far as Ireland is concerned, there is also a strong feeling that much more might have been done to secure medical benefits, and this is emphasised by the Dublin Trades Council which, on Dec. 4th, passed a resolution emphatically condemning the Irish Parliamentary Party "in their action in depriving Irish workers of the medical benefits of the Insurance Bill."

Appointment of an Assistant Medical Officer of Health of Dublin.

The corporation of Dublin has appointed Mr. M. J. Russell assistant medical officer of health of Dublin, to give his whole time to the duties of the office. The superintendent medical officer is not a whole-time officer, nor has he previously had the assistance of any medical man other than that given by the dispensary medical officers in their own districts.

Pigs and the Public Health.

The Dublin corporation at its last meeting adopted an important report of its public health committee dealing with the keeping of pigs in the city. A disregarded by-law of the corporation provides that pigs shall not be kept anywhere in the city within 50 feet of a dwelling. There are at present in Dublin some 500 piggeries, containing about 5000 pigs, about three-fourths of these piggeries, according to the public health committee, being situated within the 50 feet limit. To avoid interfering with the important industry of pig-rearing, the committee recommended, and the corporation agreed to, the suspension of the by-law. The

Local Government Board has expressed its disapproval of this step, while the council of the Dublin Sanitary Association has expressed the opinion that the keeping of swine under such conditions necessarily constitutes a nuisance within the meaning of the Public Health Act. The public health committee, however, is "under the impression that pigs kept in scrupulously clean surroundings are not any source of danger to public health." But what guarantee has the public that the piggeries are kept in even moderately clean condition?

A Bishop on the Election of Medical Officers.

The Most Rev. the Bishop of Ardagh has addressed a letter to the members of the Longford board of guardians in which he asks the guardians to elect no candidate that fails to prove (*a*) high-class medical learning, as shown in diplomas and testimonials; (*b*) morality, especially social virtue and sobriety; and (*c*) a kind and gentle disposition in dealing with the poor; and in the second place to give the appointment to the candidate who possesses the above qualifications in the highest degree.

Claim of Privilege by Medical Witness Allowed.

A claim of privilege was successfully made by a medical man in a magisterial court at Bray last week. Dr. C. Brew, who was summoned as a Crown witness in the case of a young woman charged with the murder of her child, on being sworn, said that anything he knew about the girl as her medical attendant was of a purely confidential nature and he considered that he was privileged not to give evidence in regard to it. District Inspector Molony submitted that Dr. Brew had no right to claim privilege in the case of homicide or infanticide. The state of the defendant was distinctly relevant to the point at issue. The magistrate, however, held that Dr. Brew was privileged not to give evidence, and gave him leave to withdraw.

Health of Belfast.

The report of the medical officer of health on the health of Belfast between Oct. 15th and Nov. 18th, presented to a meeting of the city council on Dec. 1st, showed that 267 cases of infectious disease had been notified, viz.: 4 of typhus fever, 15 of typhoid fever, 159 scarlet fever, 4 of simple continued fever, 44 of diphtheria, 2 of membranous croup, and 39 of erysipelas. Also 39 cases of pulmonary tuberculosis had been notified. During this period the death-rate of Belfast from all causes was 16·4 per 1000, from chest affections 5·4, and from zymotic diseases 1·2. The cases of infectious disease notified are 55 in excess of the number notified in the preceding month, and 51 in excess of the number notified in the corresponding month of 1910. This increase is mainly due to scarlet fever, the number of cases of which is 59·55 per cent. of the total cases notified.

The Water-supply of Belfast.

At a meeting of the Belfast Association of Engineers held on Nov. 23rd curves of the rate of increase of population of Belfast and of the consumption and supply of water of the city for the past 20 years were shown, and the probable future requirements for the next 10 years were indicated. These curves demonstrated the accuracy of the estimate of Mr. Macassey, late engineer of the Water Board, who in his report to the Water Commissioners of Belfast in 1891 showed the necessity for constructing a reservoir in the Silent Valley of the Mourne Mountains and having it in full operation in 1907. He calculated that in 1906 the consumption would almost equal the supply of 16½ million gallons per day drawn from the Woodburn and Stoneyford reservoirs, with the additional 3 million gallons brought down in the Mourne conduit. Further, it was established that had the Water Commissioners acted on the advice of their late engineer the city would not now be depending on a restricted supply. A critical stage has been reached, for the demand in Belfast has exceeded the supply by about 2 million gallons a day, and the city is dependent on wet weather to fill the reservoirs and keep them full. It is stated that plans are being got ready by the Commissioners for constructing a new reservoir, but it will take four or five years to complete it, and if the population of Belfast goes on increasing a second reservoir will be needed in 1921, by which time the consumption will have increased to 18 or 20 million gallons a day, and this would mean financially an expenditure of perhaps another £1,000,000. The general feeling of the engineers at this meeting was that some quick scheme should be temporarily installed, and they favoured pumping the water of Lough Neagh, and with a few miles of 24 in. pipe connecting this up to the Stoneyford system, which could deliver 4½ to 8 million gallons a day to Belfast at a fraction of the cost of the Silent Valley reservoir. Professor W. StC. Symmers was quoted to the effect that the sterilising effect of the sun's rays on the vast expanse of Lough Neagh was quite sufficient to render its waters fit for drinking purposes. What is good enough for Lurgan, with a 17·5 death-rate, should be safe for Belfast, with a death-rate of 18·6.

A New Medical Guild in Belfast.

A circular has just been issued to the general practitioners of Belfast for a preliminary meeting to be held in the Medical Institute on Dec. 7th for the purpose of organising a union or guild for the object of promoting and safe guarding the interests of all.

Epidemic Disease in Dundalk.

On Nov. 28th, at a meeting of the Dundalk urban council, reports received from the medical officers showed a marked increase in the occurrence of erysipelas, scarlet fever, enteric fever, and especially of diphtheria, of which since the last meeting 10 cases had been notified. No cause has so far been found for the epidemic, but it has been decided to summon weekly meetings of the sanitary committee during the outbreak, and to call a special meeting of the urban council to consider a report on the sanitary arrangements from the Local Government Board's medical inspector.

Dec. 5th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Consumption of Alcohol in 1910.

THE Ministry of Finance has just prepared the statistics of the production and consumption of alcohol during the year 1910, and as I have often remarked in this column statistics of this class do not make pleasant reading, for the use of spirituous liquors is steadily increasing in France. In the year 1910 the consumption exceeded that of 1907 by 110,000 hectolitres of pure alcohol—an increase of nearly 10 per cent. in four years. This, moreover, is only the quantity recorded for fiscal purposes and there will have to be added to the foregoing figures the amounts used by the *bouilleurs de cru*. However that may be, the average consumption of pure alcohol per head of the population, as recorded for fiscal purposes, was 3·59 litres last year, 3·46 litres in 1909, 3·44 litres in 1908, and 3·31 litres in 1907. The departments in which the use of spirituous liquors is most prevalent are here shown in the order of the average officially recorded consumption per head of the population: Seine Inférieure, 12·11 litres; Calvados, 9·38 litres; Somme, 9·36 litres; Eure, 9 litres; Pas de Calais, 8·44 litres; Oise, 7·92 litres; Manche, 7·28 litres; Eure et Loir, 7·15 litres; Aisne, 6·71 litres; Mayenne, 6·37 litres; Orne, 6·27 litres; Côtes du Nord, 5·64 litres; Finistère and Ille et Vilaine, 5·46 litres; Seine et Oise, 5·18 litres; Sarthe, 4·80 litres; Ardennes, 4·77 litres; Nord, 4·51 litres; Seine et Marne, 4·43 litres; Marne, 4·34 litres; and Seine, 4·25 litres. In the other departments the average consumption per head is less than 4 litres. In Gers it is only 0·70 litre; in the Landes, 0·81 litre; in Corrèze, 0·84 litre; in Vendée, 0·85 litre; in Lot et Garonne, 0·88 litre; in Lot, 0·92 litre; in Dordogne, 0·95 litre; and in Tarn et Garonne, 1·01 litre. As regards the relative consumption in town and country, the average per head of the population was 2·97 litres in the country and 4·96 litres in towns.

A Question of Medical Fees.

The seventh chamber of the Tribunal of the Seine has recently decided a legal question relative to medical fees under the following circumstances. On the recommendation of his ordinary medical adviser a gentleman had his son examined by Professor Duval, who thereupon said that an immediate operation in a private hospital was necessary. The operation was successful and the father of the patient paid the surgeon's fees. The ordinary medical adviser at the same time claimed 1200 francs for attendance on the patient before the operation, for being present at the operation, and

for visiting the patient up to the time of his discharge from the hospital. The father offered 800 francs, saying that as he had not asked his ordinary medical adviser either to be present at the operation or to visit the patient afterwards, he did not, in fact, owe anything under these two heads. The tribunal gave judgment in favour of the father, with the remark that attending at an operation and paying visits without the request of the family did not render the family liable to pay fees for such attendance and visits.

Monument to Dr. Guinard.

Last summer I referred in this column to the murderous attack on Dr. Guinard, one of the surgeons of the Hôtel Dieu—an attack which unfortunately caused his death. Immediately afterwards a subscription list was opened for the purpose of erecting a monument to him in the court of the Hôtel Dieu, probably on the very spot where he fell. The subscriptions already amount to 13,000 francs, and it is hoped that 20,000 francs may be collected, for there are several medical societies which have not yet signified their intention of contributing; it is also expected that the General Council of the Seine and the municipal council will make liberal grants.

Workmen's Associations and Tuberculosis.

In the belief that he was acting for the best M. Delcassé, the Minister of Marine, on Oct. 20th issued a circular to the ports having for its object the retirement of workmen suffering from tuberculosis. Compensation was to be granted to men discharged under these circumstances at the rate of 27 centimes per day for patients in the first stage of the disease, 54 centimes for those in the second stage, and 81 centimes for those in the third stage. The scale of compensation was not objected to, but the workmen's association at the port of Brest held a meeting and decided to agitate against the discharge of men suffering from tuberculosis and against the dispersal of men on half pay. Other similar associations followed this example. The workmen at Rochefort issued an appeal in which they said that if any of them were tuberculous they had become so in the service of the State as employer, and that their disease was due to overwork and to the unwholesome state of the buildings in which their duties were carried on. They furthermore argued that the State in the capacity of an employer ought not to set so bad an example to private employers.

Presentation to Professor Hayem.

Many professors of the Faculty of Medicine, the director of the Assistance Publique, hospital physicians, and the majority of the pupils of the eminent clinical teacher, Professor Hayem, assembled on Nov. 19th at the Hôpital Saint Antoine for the purpose of presenting him with a medal struck on the occasion of his retirement from the position of professor and hospital physician. The medal is the work of the sculptor, Roger Bloche. On one side it represents a bust of the professor and on the other side it shows him lecturing in the amphitheatre with the most celebrated of his pupils in the background. Dr. Milard, who presided, gave an outline of Professor Hayem's distinguished scientific career, and in particular the discovery of the physiological serum which bears his name. Professor Landouzy recalled the fact that Professor Hayem's grandfather had been a celebrated physician. Other addresses were then delivered by M. Mesureur, M. Dastre, Professor Barrié, Professor Gilbert, and Dr. Letulle. Professor Hayem, speaking with much emotion, expressed his thanks to his friends, colleagues, and pupils, with special reference to the organisers of the presentation, Dr. Gaston Lion and Dr. Bensaude.

Disorderly Scenes at the Lectures of M. Nicolas.

The disturbances created by the medical students at the lectures of M. Nicolas have begun again worse than ever. The students say that their professor, although distinguished as an embryologist, is not an anatomist, and they find fault with the time-table arrangement of the classes. For instance, instruction in osteology, which was carried on for two months at the amphitheatre of Clamant, now lasts only 16 days since the introduction of the system followed by M. Nicolas. They also complain that the dissecting-room subjects are so imperfectly injected as to be in a sorry condition when brought out. As the disturbances were becoming worse, the lectures of M. Nicolas have been provisionally suspended until Dec. 8th.

Dec. 4th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Physiological Effects of Balloon Ascents.

Dr. Flemming, of the Emperor William Academy in Berlin, has published an account of physiological and pathological observations made by him during balloon excursions, the ascents having been undertaken for the purpose of ascertaining the influence of high altitudes on the human body. He said that although balloon ascents are of frequent occurrence, experiments of this particular kind have nevertheless been rather uncommon in consequence of the fact that at great elevations some of the psychical faculties are weakened and the bodily energy becomes paralysed. No actual pain is felt, but the result is a state of apathy which renders the occupants of the car unfit for scientific work. Inhalation of oxygen, however, restores the normal psychical state The symptoms are, in fact, very like those observed in anæmic persons and are produced by a deficient supply of oxygen to the cerebral cortex. In anæmia the carriers of the oxygen—namely, the red corpuscles of the blood—are insufficient to convey the necessary amount of oxygen to the cortex, whilst at high altitudes a similar effect is produced by the diminished supply of oxygen in consequence of the rarefaction of the air. In Dr. Flemming's experience one of the symptoms observed at a great elevation was well-marked cyanosis of the skin, the mucous membranes, and the hands, which began to appear at a height between 4000 and 5000 metres. The pulse became very frequent, but inhalation of oxygen from a supply carried in a gas bottle brought its rate down to that which is usual on awaking after a quiet rest in bed. When the administration of oxygen was irregular or was commenced too late, then the frequency of the pulse became diminished, but not to the low rate of 68 beats per minute, as was the case when the supply of oxygen had been regular from the beginning. The respiration became more frequent with the increasing rarefaction of the air and also more superficial and irregular. This was partly caused by the deficiency of oxygen, which made the muscles less active; the insufficient oxidation of the tissues also led to the formation of certain products which had an irritant effect on the motor centres of the spinal cord. The respiration was also embarrassed by the expansion of the intestinal gases, as was shown by measuring the circumference of the abdomen. Dr. Flemming remarked that the red corpuscles of the blood were generally supposed to increase in number during residence in mountain resorts, but in the course of his balloon ascents he found that they decreased from 5,800,000 per cubic millimetre on the low ground, to 3,388,000 at an altitude of 8910 metres. This was, in his opinion, due to the fact that the low temperature of − 40° C. at that altitude produced a contraction of the capillary vessels of the skin, so that they became pervious only for the plasma of the blood but not for the corpuscular elements, the temperature and not the altitude being thus the decisive factor. It was remarkable that this low temperature was supported without much difficulty and without a feeling of intense cold, the cause being the dryness of the air and the intensity of the sun's rays, especially of the calorific ultra-red rays. The ultra-violet rays sometimes produced severe dermatitis; some of the balloonists suffered from conjunctivitis, but Dr. Flemming, who had protected his eyes by green-yellow glasses, fortunately escaped it. In conclusion, he described some interesting bacteriological experiments on the influence of the sunbeams on certain pathogenic micro-organisms, especially on pure cultures of the bacilli of enteric fever and cholera, bacillus pyocyaneus, bacillus prodigiosus, and the tubercle bacillus. In the result it was found that by exposure to the sun's rays the bacillus prodigiosus was destroyed after one hour and a quarter on the low ground and after only 20 minutes at an altitude of 5000 metres; for the bacillus of cholera the corresponding periods were one hour and a half on the low ground and one hour at the high altitude; while for the bacillus of enteric fever the periods were an hour and a half on the low ground and 20 minutes at the high altitude. Dr. Flemming then made an experiment on the influence of sunbeams on the development of tuberculosis. He found that the incubation period of tuberculosis was lengthened

by three and a half weeks when an emulsion of tubercle bacilli was exposed on the low ground for 15 minutes, and that tuberculosis did not develop at all after an exposure of the emulsion for 60 minutes. In contrast with this he found that an exposure for five minutes at an altitude of 5000 metres was sufficient to prevent the development of tuberculosis altogether. The bactericidal action of the sun's rays at the high altitude was therefore far greater than on the low ground. Dr. Flemming moreover remarked that at high altitudes wounds usually healed rapidly; furuncles and the pustules of acne also disappeared owing to the destruction of pathogenic germs.

Death of Professor Fraenkel.

Dr. Bernhard Fraenkel, formerly professor of laryngology and director of the laryngological clinic of the University of Berlin, died in that city on Nov. 11th, as mentioned in the last issue of THE LANCET. Professor Fraenkel was the son of a medical practitioner and was born in 1841 at Elberfeld in Rhenish Prussia. He obtained his professional qualifications in Berlin and settled there, first as a general practitioner, in which capacity he soon rose to a prominent position, but eventually specialised in laryngology. He served in the wars of 1864, 1866, and 1870–71, after the last of which he was appointed a *privat-docent* and became physician to the Augusta Hospital. In 1884 he was promoted to be professor; in 1887 he became director of the policlinic, and in 1893 director of the clinic for laryngology, then newly instituted in connexion with the University. For reasons of age and of health he resigned his appointment some six months ago. Among the various subjects to which Professor Fraenkel gave his attention mention may be made of his work on the anatomy of the nose, on the connexion between asthma and diseases of the nose, on cancer of the larynx, on the histology of the vocal cords, and on tuberculosis of the pharynx. In 1894 he founded the *Archiv für Laryngologie* and the Berlin Laryngological Society, of which he was the president until his death. He, moreover, did valuable work in connexion with tuberculosis, especially by advocating sanatorium treatment. He was the founder of the Berlin Sanatoriums Society, a member of the International Association for the Prevention of Tuberculosis, and co-editor of the two journals *Tuberculosis* and *Zeitschrift für Tuberculose*. Formerly he took an active part in movements for improving the position of the medical profession, being one of the founders and a member of the committee of the Deutscher Aertzevereinsbund. For 25 years he was the first secretary of the Berlin Medical Society. His death is generally regretted.

Attempted Murder of a Medical Man.

That club practice in Germany is far from being remunerative is generally admitted, and a recent incident has shown that the holder of such a position may even go in peril of his life. The event in question occurred at Essen, in Rhenish Prussia. A medical man on going home from the railway station was followed by a man unknown to him, and at the door of his house a shot was fired at him, the bullet lodging in his chest. His assailant then took to flight, but was arrested, and found to be a member of a sick club. The victim of this outrage is a medical officer of this club and had incurred the resentment of the club member by declining to certify him as being ill, with the result that the club refused to make him an allowance of sick pay.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Clinical Teaching in Neurology.

THE Swiss Federal (State) examinations for the licence to practise medicine in Switzerland ("praktischer Arzt") are at present under revision, and Swiss neurologists are making efforts to secure a proper representation of the specialty of neurology. Dr. Veraguth, lecturer on neurology (*privat-docent*) at the University of Zürich, has worked out propositions which, having been accepted by the Swiss Neurological Society, have been laid before the Society of Swiss Medical Men. He pleads for a better education of the medical student in neurology, including obligatory attendance at a neurological clinique—still a desideratum,—a half-year course at a neurological out-patient department, and lectures on neurology and medical psychology. These propositions have not been accepted by the Federal Examination Commission, which considers the medical student already overburdened with a series of new subjects, such as dermatology and legal medicine, and they have also encountered sharp opposition both on the part of clinical teachers as well as from the professors of mental medicine. The former, with Professor Sahli as representative, hold that neurology should continue to be taught by the professor of clinical medicine, with the assistance of an experienced neurologist. Professor Sahli, at the annual meeting of the Neurological Society held at Bern on Nov. 11th and 12th, emphasised the detriment caused by further specialisation, calling Dr. Veraguth's proposition an attack on the teachers of clinical medicine. The latter, with Professor Forel as spokesman, at a meeting of the Swiss Psychiatric Society held at Zürich on Nov. 25th and 26th, declared that neurology should remain dependent on the professorship of mental medicine, but should be duly enlarged in scope by the establishment of neurological clinics and policlinics under capable sub-professors and medical assistants. Professor Forel objected to having the subject of nervous diseases further split up, lest one morbid condition—for example, hysteria—should be demonstrated to the student at three clinics from three different points of view both as regards definition and treatment. It is probable that several years will still elapse before the conflicting views on this important subject can be harmonised.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

A Strike of Scavengers.

THE work of the familiar "White Wings," so named from their white drill uniform, who do the street cleaning of the city of New York, having caused great annoyance to pedestrians and others from the flying dust, the hours of the brigade were changed to eight hours between sunset and sunrise. Although these men are extremely well paid for unskilled work—viz., 818, or £3 12*s.*, a week—the change in their hours moved them to strike. In less than 48 hours the accumulation of filth, especially in the east side of the city, was appalling, and the people were threatened with all the troubles of filth-borne diseases. To the surprise of the strikers, it was pointed out to them that they were civil service employees and were consequently somewhat in the position of soldiers or sailors, a strike among whom means mutiny. "Strike breakers" were promptly imported by the thousand, under whose efforts, extending over a week, the piles of garbage were removed. The misled strikers now find themselves forced out of good employment by the automatic succession of the men following them upon the civil service list. It is likely that New York will be spared a similarly dangerous strike for many years to come.

Transplantation of a Human Kidney.

Although Dr. L. J. Hammond, of the Methodist Episcopal Hospital of Philadelphia, has not yet given an official account of his work, it is well known that on Nov. 13th he transplanted a kidney from the body of a man recently killed in an automobile accident to that of a patient afflicted with renal tuberculosis, with the immediate result of anastomosis of vessels and other satisfactory consequences. Dr. Hammond had a large audience of American and Canadian surgeons who were attending the Clinical Congress at Philadelphia, during which an immense number of major operations were performed.

A Christian Science Home.

A statement made in a former of these letters to the effect that a home for Christian Scientists had been founded in the State of New York has elicited expressions of doubt. The New York evening papers of Oct. 6th published as news a paragraph, of which the following are extracts: "In Special Term of the Supreme Court, Justice Pendleton to-day signed an order approving the certificate of incorporation of the First Christian Science Home Association of the State of New York. The avowed purpose of the association, which is said to be the first of its kind in this State,

is to establish and provide suitable and homelike accommodations for men and women desirous of receiving the benefits and precepts of the late Mrs. Mary Baker Eddy. The home will exclude no one on the ground of poverty, birth, or prejudice, ... and will give shelter, food, clean and quiet surroundings to those who seek its benefits. The incorporators and directors for the first year are Lysbeth L. Campbell, of 150, West 94th-street; Regina F. Rothschild, 365, West 118th-street; Emerson P. Jennings and Susan E. Jennings, 1738, 79th-street, Bath Beach; Philip P. Major, 75, West 92nd-street; and Marguerita Markle, 152, West 98th-street."

The Crocker Bequest.

A California millionaire, who died from the effects of a malignant growth, left £200,000 to Columbia University for the establishment of a fund connected with his name and having for its object the investigation of cancer. After prolonged litigation this legacy has been confirmed, and the Faculty of Medicine, still popularly known as the College of Physicians and Surgeons, is already planning a vigorous programme.

A Seizure of Glass Eyes.

American-made glass eyes are not equal to the German article, and the trade is forced to pay a customs duty of 60 per cent. *ad valorem* on the German eyes as "decorated glass." A so-called German baron has been under suspicion for some time as a smuggler of the articles, and recently the Federal agents found a *cache* in Hoboken, New Jersey, where many of the big liners dock, of 14,000 glass eyes. The baron and a supposed accomplice were arrested and held in £1000 bail each. These imported eyes are sold wholesale at about 4*s.* each, but retail at about 1 guinea, including the fitting and careful matching in colour. Several employees of the steamship lines will probably be arraigned along with the foreign nobleman.

Another Opium Raid.

A raid was made in the Harlem district of New York on Nov. 4th on a Chinese laundry, where the usual supply of opium extract in various forms was unearthed to the tune of several hundred dollars, much of it in the familiar lychee nuts, the kernel of which is replaced with smoking opium and retails at about a shilling. The "joint" (opium den) was considered to be a particularly villainous one in furnishing an exclusive *clientèle* of negroes, who seem to be singularly susceptible to the influence of narcotics and become dangerous criminals under their use.

The Death-rate of New York.

This continues to drop, and for the week ending Oct. 31st was the lowest on record—viz., 12·12 per mille.

Personal.

Dr. David D. Scannell has resigned the assistant professorship of surgery at Tufts College, Boston, and with him the entire surgical faculty, the reason assigned being that he was not considered in the appointments made at Grace Hospital, Boston.—Dr. Simon Flexner, of the Rockefeller Institute for Medical Research, has been appointed by the German Emperor an honorary member of the Royal Institute for Experimental Therapeutics of Frankfort-on-the-Main.—Dr. William James Henry Bellamy, a popular and well-known practitioner among the fashionable winter colony of the South, died at Wilmington, N.C., on Nov. 17th.—Dr. Walter Wyman, the distinguished surgeon-general of the Public Health and Marine Hospital Service, died at Washington on Nov. 20th. He accomplished much for the sailors of the Atlantic and on the western rivers, and established the first Federal Government Sanatorium for Consumptives in New Mexico. He was a power for the general betterment of the nation's health as far as his influence was not circumscribed by his official position, and he is greatly regretted.

Nov. 22nd.

ROYAL INSTITUTION.—Dr. W. Bateson, F.R.S., has been appointed Fullerian Professor of Physiology at the Royal Institution for a period of three years. During the present winter Professor Bateson will deliver a course of six lectures before the institution on the Study of Genetics.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

The Prevention of Malaria.

THOSE who have followed the development of our knowledge regarding malaria know that there are at present in Europe two parties of propagandists with reference to the prevention of malaria. One party advocates anti-mosquito measures large and small, and the other pins its faith to the widespread use of quinine as the correct method of extirpating malaria. For some time there was a danger that, until the difference of opinion between these two parties should be settled, no very active measures against the disease would be taken by administrations. It is greatly to the credit of scientific workers in India that at this point, instead of continuing a controversy from which no useful result was likely to accrue, they disassociated themselves from both parties, and proposed the new line of action which had its beginning at the Imperial Malarial Conference held at Simla in 1909. The outstanding and highly important feature of this conference was not the list of recommendations regarding the particular measures which should, or should not, be adopted, but the founding of a permanent organisation for dealing with the disease in every chief area of the country. The organisation proposed was: (1) a central scientific committee; (2) a committee in each province; and (3) a general committee consisting of the members of the central committee and delegates from the provincial committees. The deliberations of the conference showed that the first essential in the attack against malaria in India is not the immediate initiation here, there, and everywhere of expensive anti-mosquito campaigns on the lines of those reported to have been successful in a few countries under conditions very different from those prevailing in India, but the obtaining of accurate and complete knowledge of all the circumstances connected with the disease in different areas. The central scientific committee was, therefore, appointed to direct and coördinate investigations to this end, and in the first place they made arrangements by which each province should be able to train a number of officers and subordinates in modern methods of malarial research. With this object there was established a Central Malarial Bureau, containing a museum, laboratory, and reference library, and at Amritsar a house was secured which serves as a permanent laboratory for malarial investigations and teaching. The next step was the appointment in the several provinces of some specially trained officers who would devote their whole time to the study of malaria. They have been provided with adequate working staffs, and tour from place to place investigating the disease and assisting in its prevention. In addition, specially qualified officers work directly under the auspices of the central committees. It is the duty of the former workers to ascertain exactly the malarial circumstances of different areas and state the remedies which should be applied. Two noteworthy examples of the results of such work are the reports by Major S. R. Christophers, I.M.S., on the causes of malaria in the Punjab, and by Dr. C. A. Bentley on the causes of malaria in Bombay city, and the measures necessary for its control. These have both been referred to on several occasions in THE LANCET. The more we know of malaria and the more it is studied, the more obvious becomes the conclusions that detailed investigations are essential before large sums of money are spent on schemes designed to improve malarial conditions. When, however, such investigations have been conducted and definite conclusions have been arrived at, it is the function of the provincial and general committees to ensure that satisfactory and complete action is taken upon them. The members of these committees are necessary and complementary to the scientific workers; it is their duty to spread the conclusions, to teach, to persuade, and there can be no doubt that if they do so with energy the result will not be long delayed. There is evidence that in some provinces the malarial committees have already realised their responsibilities in this respect, and one sign of this is found in the fact that the consumption of quinine in this country has increased greatly during the last two years. The most recent move is the initiation of a scheme for an Indian Research Fund, to be devoted exclusively to

researches in connexion with sanitary problems, the primary object being to assist the policy of making a direct attack upon malaria and certain other of the more important epidemic diseases. It is stated that the Government of India has made a grant of five lakhs of rupees to this fund, and that one of the proposed items of expenditure will be the investigation and carrying out of various educational methods by which the people of India may be brought to realise how to protect themselves from malaria and other epidemic diseases.

Smoking in the Army.

The use of tobacco in the army is the subject of an article by Lieutenant-Colonel P. Hehir, I.M.S., in the *Journal of the United Services Institution of India*. He alleges that the imported cigarettes used by troops in this country are made from the refuse of the tobacco market. Last year, he says, one brand was sold for 20 for ½*d.*, the tobacco in them being uncured and half-rotten. There have been issued various orders by commanding officers and general officers, and in some cases the smoking of cigarettes has been prohibited at times when no restriction is made on pipe-smoking. But if it is true that cigarette-smoking is on the increase in the British and in the Indian army, some more concerted action than these spasmodic efforts is desirable. Colonel Hehir suggests that the tobacco sold in canteens, coffee-shops, regimental bazaars, and in cantonments generally, should be closely watched and controlled.

Nov. 15th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Charge Against a Medical Man.

THE trial of Dr. Samuel Peacock on a charge of murder was concluded at Melbourne before the Chief Justice and a jury after a prolonged hearing. The charge was concerned with the disappearance of a young woman who had admittedly been an inmate of a private hospital owned by the accused. The case for the Crown was that the young woman had died after an illegal operation and that the accused had secretly disposed of the body. The accused read a lengthy statement in which it was alleged that the young woman had left the hospital, and some articles of jewellery found in the accused's possession were said to have been voluntarily left behind. No trace of the body was discovered, and the evidence was almost entirely presumptive, except for certain statements made by the principal witness for the Crown who had had certain relations with the missing woman. The jury after three hours' retirement returned a unanimous verdict of "Guilty," and the accused was formally sentenced to death, although some law points are reserved for future argument. Dr. Peacock is 72 years of age.

Tenth Australasian Congress.

Dr. Arthur C. Purchas, the President-elect of the next session of Congress to be held in Auckland, New Zealand, in 1914, is a graduate of the University of Edinburgh. He was born in New Zealand, and is a son of the Rev. Arthur Purchas.

Charities Bill.

The Charity Bill introduced into the Victorian State Parliament by the Government, in which it is proposed to vest the control of finance in all charities subsidised by the Government in a board of three commissioners, passed the second reading in the Assembly, but its further progress was stopped by the dissolution of Parliament, and it must now go over until the new House meets. On the whole it has been sympathetically received, but its serious discussion was not entered upon, as it was recognised that there was no prospect of its being placed on the statute book by the present Government before the General Election.

Pure Milk.

The Victorian Minister of Health recently called a conference of municipal and other bodies to consider the question of a pure milk-supply and the establishment of municipal milk depôts for infants. Some preliminary points were discussed, and the conference adjourned for the appointment of representatives from the Victorian Branch of the British Medical Association and other public bodies, including the Australian Natives Association, a powerful friendly society in Victoria. The Lady Talbot Milk Institute, which was the pioneer movement in this line, has been proved to offer financial difficulty, and it is considered that the municipal councils could better undertake the same work. The attitude of the medical profession towards the new development has not yet been defined.

Melbourne Hospital.

The new buildings of the Melbourne Hospital are now well advanced in certain directions, and three blocks are almost complete as regards the actual construction. They consist of an administrative section and two ward-blocks, each of which is six storeys in height, constructed in brickwork. Although space has been gained by going up into the air, it is evident that the contention of those who considered the ground area too small for a large hospital is being confirmed.

Lunacy in Victoria.

The annual report of the Inspector-General for Insane in Victoria states that there has been a material increase in admissions during 1910, and that whereas 5200 registered patients were under supervision at the beginning of the year, the number at the close was 5349. The receiving house totals were 41 and 47. At the end of 1909 the ratio was 1 insane person to 250 of population, and at the end of 1910 1 to 246. The deaths numbered 368, as against 371 in the previous year. The report discusses the reasons for the high proportion of insane in Victoria. Some points set forth are the high proportion of old people in the population, the low masculinity rate, low birth-rate, and so on, but no positive conclusion is drawn. The expenditure in maintenance was £169,174, an increase of £6057 on the previous year. The Inspector-General has written to the *Australian Medical Journal*, drawing the attention of medical men to the fact that the efficiency of the receiving house is being impaired by the sending of patients who might at once be certified for admission to an asylum, and suggests that this is probably due to a wish to spare the feelings of relatives, but results in blocking the reception of cases for whom something might be effected in the way of improvement or cure.

Nov. 4th.

Obituary.

FRANCIS THOMAS BOND, M.D. LOND., M.R.C.S. ENG., F.R.S. EDIN.,

MEDICAL OFFICER OF HEALTH, GLOUCESTERSHIRE COMBINED DISTRICT, ETC.

Dr. Francis Thomas Bond died at his residence, 3, Beaufort Buildings, The Spa, Gloucester, on Tuesday afternoon last. The deceased was taken suddenly ill on the morning of Thursday, Nov. 30th, whilst waiting at the Great Western Railway Station at Gloucester for a train to Cirencester, where he was to have attended a meeting of the urban district council in his capacity as medical officer of health to the Gloucestershire Combined Sanitary District. He was sitting near the fire in one of the waiting-rooms at the time when he suddenly collapsed, and medical aid having been summoned he was conveyed to his residence. It was found that he had had a slight paralytic stroke, and although his condition improved somewhat he afterwards became worse, passing peacefully away, as stated, on Tuesday afternoon.

The late Dr. Bond was in his seventy-eighth year. He took his Bachelor of Arts degree in 1853, and became a Member of the Royal College of Surgeons of England in 1856, his education and training having been obtained at Queen's College, Birmingham; St. Mary's Hospital, London; as well as in Paris and Edinburgh. He took his M.B. degree (being awarded the medal in physiology) in 1857 at the University of London, where he became M.D. in 1860. Subsequently he became a Fellow of the Royal Society of Edinburgh, and a Fellow of the Chemical Society. For a time he was physician and professor of clinical medicine at Queen's Hospital, Birmingham, and was also professor of chemistry and Dean of Faculty at Queen's College. Later Dr. Bond held an important educational appointment in the south of England, being for some time Principal of the Hartley Institute, Southampton, and this he gave up with a view of devoting himself to sanitary work, which he entered on in 1873, when, upon the formation by

the Local Government Board of the Gloucestershire Combined Sanitary District (which then consisted of 13 local sanitary authorities), he was, out of a large number of candidates, appointed its first medical officer of health, which responsible position he retained to the time of his death. During the period of close upon forty years in which Dr. Bond acted in this capacity he gained an experience of sanitary matters connected with Gloucestershire which is surely unrivalled, and as an expert upon public health questions generally he was properly held in very high esteem. He devoted himself whole-heartedly to the work, and his death comes as a great loss to the various local authorities who had for so long a period had the advantage of his valuable store of knowledge.

Amongst other positions which he had held in the course of a long and busy professional career were those of president of the West of England and South Wales Branch of the Society of Medical Officers of Health, of the Midland Association of Medical Officers of Health, and of the Gloucester Branch of the British Medical Association. Dr. Bond took an especial interest in the question of vaccination, the cause of which he was ready at all times and upon all occasions to champion, and he was prominently associated with the formation of the Jenner Society, of which he was the honorary secretary. He was a prolific writer upon scientific and other questions. Among his many publications may be mentioned contributions on the "Pathology of Rheumatism" in 1858 and the "Pathology of Chorea" in 1860; a translation of "Radicke on Medical Statistics"; "Notes on Water Filtration" in 1875; "A Plea for the More General Practice of Skipping as an Unsurpassed Form of Home Gymnastics" in 1906; and "Gloucester Mineral Spa: its History and Capabilities," issued for private perusal about the year 1906.

Dr. Bond did a good deal in the direction of bacteriological research and experimental work, and was of an inventive turn of mind. Among other things he patented a filter, and a hygienic quilt. He also identified himself with scientific agriculture, and more especially the dairy industry; and he evolved a method of cheese manufacture with which he was associated for a number of years. He leaves a widow, one son, and a daughter.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Adam Szulislawski, extraordinary professor of ophthalmology in the University of Lemberg.—Dr. Charles Throw, adjunct professor of ophthalmology and otology in the University of Toronto.—Dr. A. F. Legendre, of the French Colonial Medical Service, who was sent by the Government on a scientific mission to China, massacred by the Lolos in Hong Chouei Tong.—Dr. Néjolov, professor of midwifery and gynæcology in the University of Warsaw.—Dr. Hans Hammerstein, formerly assistant to Dr. Nagel, professor of gynæcology, of diphtheria contracted from a patient. In spite of the most skilful treatment death occurred in two days.—Dr. Hennigsen, of Gehren, president of the Thüringen Medical Association.

Medical News.

UNIVERSITY OF LONDON.—At the M.D. examination for internal and external students the following candidates were successful:—

Branch I., Medicine.—Phirozshaw Cooverji Bharucha, B.S., University College Hospital; John Webster Bride, B.S., Victoria University of Manchester; Manchersha Dhanjibhai Dorabji Gilder, B.S., University College Hospital; Alexander Edward Gow, B.S., St. Bartholomew's Hospital; Frederick William Higgs, B.S., St. George's Hospital; Ernest Williams Jones, University of Birmingham; David Judah, B.S., and Clement Lovell, B.S., University College Hospital; and Geoffrey Viner, B.S., and Arthur Lowndes Yates, B.S., St. Bartholomew's Hospital.

Branch IV., Midwifery and Diseases of Women.—Elsie Mary Chubb, B.S., London (Royal Free Hospital) School of Medicine for Women; Joseph Bernard Dawson, B.S., University of Birmingham and St. Bartholomew's Hospital; William Poole Henley Munden, B.S., Guy's Hospital; John Hobart Nixon, B.S., St. Mary's Hospital; Alfred Howard Parkinson, B.S., B.Sc., University of Leeds; and Robert Evans Thomas, B.S., University of Bristol.

Branch V., State Medicine.—Alfred Ball, B.S., and Walter Francis Corfield, B.S., University College Hospital; Matilda Hunt, B.S., London (Royal Free Hospital) School of Medicine for Women and Royal Institute of Public Health; James Jenkins Paterson, B.S., B.Sc., University of Liverpool; Alfred Charles Foster Turner, B.S., St. Thomas's Hospital; Wentworth Francis Tyndale, St. George's Hospital; Thomas Williams Wade, B.S., University College, Cardiff, and Charing Cross Hospital; and Cuthbert Ferguson Walker, B.S., St. Mary's Hospital and Victoria University of Manchester.

Branch VI., Tropical Medicine.—Daniel Elie Anderson, B.A., B.Sc., London School of Tropical Medicine; Francis Victor Owen Beit, St. Bartholomew's Hospital and London School of Tropical Medicine; Friedrich Gröne, St. Bartholomew's Hospital; John Hanna Murray, University College Hospital and London School of Tropical Medicine; and Charles Cecil Connock Shaw, B.S., St. Mary's Hospital, London School of Tropical Medicine, and Post Graduate College, West London Hospital.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

UNIVERSITY OF BRISTOL.—At the Autumn Congregation the following medical degrees were conferred. The candidates were presented by the Dean of the Medical Faculty, Professor Edward Fawcett.

M.D.—J. F. Blackett and Latimer J. Short.
M.S.—C. A. Joll.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Umber has been appointed Director of the Medical Department of the West-end Hospital, Charlottenburg, in succession to the late Dr. Grawitz.—*Bonn:* Dr. A. Machol has been appointed Oberarzt of the University Surgical Clinic, in succession to Dr. Stich, who is going to Göttingen; and Dr. Rudolf Finkelnburg has been appointed Director of the Hydrotherapeutic Institute in connexion with the University Medical Clinic, in succession to Dr. Julius Strasburger, who is migrating to Breslau.—*Clausenburg:* Dr. Elemer Veress has been appointed Extraordinary Professor of Biology; and Dr. Genersich and Dr. Reinbold have been granted the title of Extraordinary Professor.—*Göttingen:* Dr. Wilhelm Tintemann has been appointed Oberarzt of the Provincial Asylum, where instruction is given to the University students in Mental Diseases.—*Königsberg:* Dr. R. Haecker has been recognised as *privat-docent* of Surgery.—*Leipsic:* Dr. Läwen has been appointed Director of the Surgical Department of the new St. George's Hospital.—*Marburg:* Dr. F. A. König, of Greifswald, has been appointed to the chair of Surgery, in succession to Dr. Friedrich.—*Moscow:* Dr. A. W. Grigorieff, of Warsaw, has been appointed to the chair of Forensic Medicine.—*Pisa:* Dr. F. Cavazzi has been recognised as *privat-docent* of External Pathology.—*Philadelphia (University of Pennsylvania):* Dr. T. T. Thomas has been appointed Adjunct Professor of Anatomy, in succession to Dr. Davis.—*Prague (German University):* Dr. Karl Zörkendörfer, of Marienbad, has been recognised as *privat-docent* of Balneology and Hygiene.—*Sienna:* Dr. F. Melocchi has been recognised as *privat-docent* of Internal Pathology.—*Vienna:* Dr. O. Porges has been recognised as *privat-docent* of Medicine.

LANGHO REFORMATORY.—At the annual meeting of the Lancashire Inebriates Acts Board held recently at Preston, the chairman stated that after seven and a half years' practical experience at Langho of the working of the present Act they were in a position to judge of its merits and its defects. The number of the inmates had increased. It contained fundamental defects and omissions which practically rendered it valueless, a view that had been endorsed by more than one Parliamentary committee. The Home Secretary had expressed the hope that he might be able to press forward legislation on the subject next session. Many of the failures were due to the women being sent to the reformatory late in life, and also to their not being looked after when they came out. Many of the women inmates were irreformable, and present-day legislation could not effectively deal with them.

REUBEN HARVEY MEMORIAL PRIZE.—The tenth award of this triennial prize will be made on July 1st, 1912. The competition for the prize is open to all students of the various schools of medicine in Dublin which are recognised by the medical licensing bodies in Ireland, and also to graduates or licentiates of these bodies of not more than three years' standing at the time of the award. The prize, value £25, will be awarded to the writer of the best essay, on a subject to be selected by the candidate, evidencing original research in animal physiology or pathology; the

essay to be illustrated by drawings or preparations. The essays, bearing fictitious signatures, are to be lodged with the Registrar of the Royal College of Physicians of Ireland, Dr. T. Percy C. Kirkpatrick, Kildare-street, Dublin, on or before June 1st, 1912.

THE death occurred with painful suddenness at Billingshurst, Sussex, on Nov. 22nd, of Mr. William Henry Hubert, M.R.C.S.Eng. He was a very keen hockey player, and while taking part in a game he suddenly fell backwards and expired immediately. Mr. Hubert was most highly respected. For very many years he had practised in the above district and he held a number of local appointments. After studying at St. George's Hospital Mr. Hubert qualified in 1868.

THE EMPRESS MARIE FÉODOROVNA FUND.—This fund was founded during the Seventh International Red Cross Conference, held at St. Petersburg in 1902, by Her Imperial Majesty the Empress Marie Féodorovna, the August Protectress of the Russian Red Cross Society, for the purpose of awarding prizes to the authors of the best inventions having for their object the diminution of the sufferings of the sick and wounded in time of war. The next competition will be held in connexion with the Ninth International Red Cross Conference to be held at Washington, D.C., from May 7th to 17th, 1912, where the inventions of competitors will be displayed. There are three prizes of approximately £600, £300, and £100. Full particulars of the subjects for competition can be obtained from the secretary, 9, Victoria-street, London, S.W.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The National Insurance Bill.

UNDER the closure resolution of the House of Commons the guillotine fell upon the report stage of Part I. of the National Insurance Bill on the evening of Thursday, Nov. 30th. This part covers the whole field of National Health Insurance, and in the closure resolution it was included with the proposed new clauses in the first compartment of time devoted to the Bill. However, the full time—two and a half days—was, in fact, given to the new clauses, and not a single line of Part I., as it emerged from committee, was discussed before the guillotine fell. The Chancellor of the Exchequer had about 470 amendments standing on the notice paper in his name. These were put from the chair one by one, and declared to be carried. The Opposition, refraining from the task of forcing divisions, retired from the House after a protest. The numerous changes thus made in the Bill introduce further complexity into it, and their cumulative effect could not be estimated until the measure as amended had been printed.

The Administration of Medical Benefit.

Clause 16 deals with the administration of medical benefit. As amended by the introduction of the changes proposed by the Chancellor of the Exchequer it reads as follows:—

"1. Every Local Health Committee shall for the purpose of administering medical benefit make arrangements with duly qualified medical practitioners in accordance with regulations made by the Insurance Commissioners.

"2. The regulations made by the Insurance Commissioners shall provide for the arrangements made being subject to the approval of the Insurance Commissioners and being such as to secure that insured persons shall, save as hereinafter provided, receive adequate medical attendance and treatment from the medical practitioners with whom arrangements are so made and shall require the adoption by every Local Health Committee of such system as will secure:—(*a*) the preparation and publication of lists of medical practitioners who have agreed to attend and treat insured persons whose medical benefit is administered by the committee; (*b*) a right on the part of any duly qualified medical practitioner who is desirous of being included in any such list as aforesaid of being so included, but where the Insurance Commissioners, after such inquiry as may be prescribed, are satisfied that his continuance in the list would be prejudicial to the efficiency of the medical service of the insured, they may remove his name from the list; (*c*) a right on the part of any insured person of selecting, at such periods as may be prescribed, from the appropriate list the practitioner by whom he wishes to be attended and treated, and, subject to the consent of the practitioner so selected, of being attended and treated by him; (*d*) the distribution amongst and, so far as practicable, under arrangements made by the several practitioners whose names are on the lists of the insured persons who after due notice have failed to make any selection, or who have been refused by the practitioner whom they have selected; (*e*) the provision of medical attendance and treatment, on the same terms as those arranged with respect to insured persons, to members of any friendly society which becomes an approved society who were such members at the date of the passing of this Act and who are not entitled to medical benefit under this part of this Act by reason either that they are of the age of 65 or upwards at the date of the commencement of this Act, or that being subject to permanent disablement at that date they are not qualified to become insured persons.

"Provided that if the Insurance Commissioners are satisfied after inquiry that the practitioners included in any list are not such as to secure an adequate medical service in any area, they may dispense with the necessity of the adoption of such system as aforesaid as respects that area, and authorise the committee to make such other arrangements as the Commissioners may approve; or the Commissioners may themselves make such arrangements as they think fit, or may suspend the right to medical benefit in respect of any insured persons in the area for such period as they think fit, and pay to each such person a sum equal to the estimated cost of his medical benefit during that period, and where the Commissioners take any such action themselves they shall retain and apply for the purpose such part of the sums payable to the Local Health Committee in respect of medical benefit as may be required.

"3. The regulations made by the Insurance Commissioners shall authorise the Local Health Committee by which medical benefit is administered to require any persons whose income exceeds a limit to be fixed by the committee, and to allow any other persons, in lieu of receiving medical benefit under such arrangements as aforesaid, to make their own arrangements for receiving medical attendance and treatment (including medicines and appliances), and in such case the committee shall, subject to the regulations, contribute from the funds out of which medical benefit is payable towards the cost of medical attendance and treatment (including medicines and appliances) for such persons sums not exceeding in the aggregate the amounts which the committee would otherwise have expended in providing medical benefit for them.

"4. The regulations shall provide that, in the case of persons who are entitled to receive medical attendance and treatment under any system or through any institution existing at the time of the passing of this Act, and approved by the Local Health Committee and the Insurance Commissioners, such medical attendance and treatment may be treated as, or as part of, their medical benefit under this part of this Act, and may provide for the committee contributing towards the expenses thereof the whole or any part of the sums which would be contributed in the case of persons who have made their own arrangements as aforesaid, so, however, that such regulations shall secure that no person be deprived of his right, if he so elects, of selecting the duly qualified medical practitioner by whom he wishes to be attended and treated, in accordance with the foregoing provisions of this section.

"5. Every such committee shall also make provision for the supply of proper and sufficient drugs and medicines and prescribed appliances to insured persons in accordance with regulations made by the Insurance Commissioners, which shall provide for the arrangements made being subject to the approval of the Insurance Commissioners, and being such as to enable insured persons to obtain from any persons, firms, and bodies corporate with whom arrangements have been made such drugs, medicines, and appliances if ordered by the medical practitioner by whom they are attended, and shall require the adoption by every Local Health Committee of such a system as will secure—(*a*) The preparation and publication of lists of persons, firms, and bodies corporate who have agreed to supply drugs, medicines, and appliances to insured persons whose medical benefit is administered by the committee, according to such scale of prices as may be fixed by the committee; (*b*) a right on the part of any person, firm, or body corporate desirous of being included in any such list as aforesaid, of being so included for the purpose of supplying such drugs, medicines, and appliances as such person, firm, or body corporate is entitled by law and authorised by the committee to supply except in cases where the Insurance Commissioners after inquiry are satisfied that the inclusion or continuance of the person, firm, or body corporate, in such list would be prejudicial to the efficiency of the service: Provided that—(i) If the Insurance Commissioners are satisfied that the scale of prices fixed by the Committee is reasonable, but that the persons, firms, or bodies corporate included in any list are not such as to secure an adequate and convenient supply of drugs, medicines, and appliances in any area, they may dispense with the necessity of the adoption of such system as aforesaid as respects that area, and authorise the committee to make such other arrangements as the Commissioners may approve. (ii) Except as may be provided by regulations made by the Insurance Commissioners, no arrangement shall be made by the Local Health Committee with a medical practitioner under which he is bound or agrees to supply drugs or medicine to any insured persons. (iii) Subject to the regulations made by the last foregoing proviso, the regulations shall prohibit arrangements for the dispensing of medicines being made with persons other than persons, firms, or bodies

corporate, entitled to carry on the business of a chemist and druggist under the provisions of the Pharmacy Act, 1868, as amended by the Poisons and Pharmacy Act, 1908, who undertake that all medicines supplied by them to insured persons shall be dispensed either by or under the direct supervision of a registered pharmacist or by a person who, for three years immediately prior to the passing of this Act, has acted as a dispenser to a duly qualified medical practitioner or a public institution. (iv) Nothing in this Act shall interfere with the rights and privileges conferred by the Apothecaries Act, 1815, upon any person qualified under that Act to act as an assistant to any apothecary in compounding and dispensing medicines.

"6. There shall in each year be paid to the Local Health Committee for each county or county borough out of moneys credited to a society which has members resident in the county or county borough such sum in respect of the medical benefit of such members and the cost of administration thereof as may be agreed between the society and the committee, or in default of agreement may be determined by the Insurance Commissioners.

"7. If in any year the amount payable to a Local Health Committee in respect of all persons for the administration of whose medical benefit it is responsible is insufficient to meet the estimated expenditure thereon the committee may, through the Insurance Commissioners, transmit to the Treasury and to the council of the county or county borough an account showing the amount so payable and the estimated expenditure, and the Treasury and the county council or the council of the county borough may, if they think fit and if satisfied that the amounts so payable and the proposed expenditure are reasonable and proper in the circumstances, sanction the expenditure.

"8. The Treasury and the council of the county or county borough sanctioning any such expenditure as aforesaid shall thereupon each be liable to make good, in the case of the Treasury out of moneys provided by Parliament, and in the case of the council of a county or county borough out of the county fund or borough fund or borough rate, as the case may be, one-half of any sums so sanctioned by them and expended by the Local Health Committee on medical benefit in the course of the year in excess of the amounts so payable to the Local Health Committee as aforesaid."

Medical Men and Health Committees.

Clause 55 deals with the Local Health Committees. After providing for the representation of insured persons, the clause as amended proceeds:—"(*c*) Two members shall be elected in manner provided by regulations made by the Insurance Commissioners, either by any association of duly qualified medical practitioners resident in the county or county borough which may have been formed for that purpose under such regulations, or, if no such association has been formed, by such practitioners; (*d*) one member or, if the total number of the committee is 60 or upwards, two members, or if the total number of the committee is 80, three members, shall be duly qualified practitioners appointed by council of the county or county borough."

The provision that of the members appointed by the Insurance Commissioners one at least shall be a medical man remains.

Medical Men as Commissioners.

By the amendments now inserted in the Bill, a medical man is to be appointed as an Insurance Commissioner in Scotland, Ireland, and Wales respectively.

The Insurance Commissioners.

The announcement that the Government had appointed Mr. J. SMITH WHITAKER to be the Deputy Chairman of the Insurance Commissioners and the Medical Commissioner was made in the House of Commons on Monday, Dec. 4th. He has become known to Members as the medical secretary of the British Medical Association during the protracted negotiations which that organisation has had with the Chancellor of the Exchequer. The chief interest in Westminster in Mr. SMITH WHITAKER'S appointment is the effect which it will have on the medical profession at large. Mr. LLOYD GEORGE is not yet in a position to give the names of the Irish, Scottish, and Welsh Commissioners.

Third Reading of National Insurance Bill.

The National Insurance Bill was read a third time in the House of Commons on Wednesday, Dec. 6th. The official Opposition brought forward a reasoned amendment to the motion for third reading. It was moved by Mr. H. W. FORSTER and was in the following terms:—"That, while approving the objects of national insurance, this House is of opinion that under Part I. of the Bill public funds and individual contributions will not be used to the best advantage of those most closely affected, and that, as the Bill has been neither adequately discussed in this House nor fully explained to the country, and would in its present form be unequal in its operation, steps should be taken to enable further consideration of Part I. to be resumed next session, and in the meanwhile to have the draft regulations published."

The debate ran largely on the question whether adequate time had been given for the thorough discussion of the measure. The Chancellor of the Exchequer maintained that all substantial points had been discussed at some stage of the proceedings on the Bill. He admitted, in a sentence, that he was not going to say that the Bill gave satisfaction to the medical profession. Ultimately the amendment was rejected by 320 votes to 223. The motion for the third reading was carried by 324 votes to 21.

The Health Visitors Bill.

The Health Visitors Bill has been withdrawn in the House of Commons without having reached a second reading.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 29TH.

National Insurance in the Highlands.

Mr. MACPHERSON asked the Secretary to the Treasury whether, in view of the fact that in the Highlands and Islands of Scotland the population was so poor and scattered, he would take steps to provide for the necessity of giving a grant in aid to the Local Insurance Committee, to be used by them to secure effective enjoyment of all the benefits of the scheme for the insured persons and fair mileage fees for doctors.—Mr. MCKINNON WOOD replied: The difficulty pointed out by my honourable friend has been met to a certain extent by the insertion of Subsection (9) of the Scottish clause, and the new clause passed last night giving power to vary benefits in certain cases; and before arriving at any conclusion as to the desirability or otherwise of special grants it seems necessary to wait for the results of these provisions.

Hospital Inmates and National Insurance.

Mr. EVELYN CECIL asked the Chancellor of the Exchequer whether he was aware that at present if a man left his lodgings and went into a hospital he got his sick pay, which was sufficient to enable him to keep on his lodgings while he was in hospital and help him to a convalescent home afterwards, but that, under Clause 14 (b) of the National Insurance Bill, if he had no dependent, his sick benefit went to the Local Insurance Committee, so that he had none of this money with which to keep on his lodgings or get to a convalescent home; and whether he proposed to make any amendment to the Bill to meet such cases.—Mr. LLOYD GEORGE wrote, in reply: The principle of sickness benefit is that it should assist a man to maintain himself and his family while incapacitated by illness. If he is being maintained without expense to himself, and has no dependents, this principle does not apply. I may remind the honourable Member that the money thus saved to the committees will be used largely in contributions to hospitals and similar institutions.

MONDAY, DEC. 4TH.

Mr. J. Smith Whitaker appointed Medical Insurance Commissioner.

Mr. JOYNSON-HICKS asked the Chancellor of the Exchequer whether the report was correct that Mr. J. Smith Whitaker, medical secretary of the British Medical Association, had been appointed a member of the Insurance Commission; and, if so, when was he first approached.—Mr. LLOYD GEORGE replied: The report is correct. Mr. J. Smith Whitaker was approached last week for the first time on the subject. He consulted the Council of the British Medical Association, and I have a letter from him dated Dec. 2nd as follows: "Having consulted the Council of the British Medical Association I have been advised by them to accept the post of Deputy Chairman of the Insurance Commission for England offered in your letter of Dec. 1st and I do so accept it on the terms stated in that letter."

Mr. JOYNSON-HICKS: May I ask whether we may assume that the British Medical Association are satisfied with the provisions of the Insurance Bill?—Mr. LLOYD GEORGE: I should not like to express an opinion on that question. At any rate the offer was made to the secretary, and the British Medical Association allowed him to accept the position.

Major ANSTRUTHER-GRAY asked whether anyone would be appointed in Scotland to represent the medical profession.—Mr. LLOYD GEORGE: We shall appoint a medical officer, though perhaps not on the same terms as in England. So far as England is concerned, the appointment has been given to one who has experience of this country.

Vaccination Topics.

Dr. PETO asked the President of the Local Government Board whether he was aware that, owing to the increase of exemptions in the three years ended Dec. 31st last, the vaccination officer of the West Bromwich union sustained a total loss of fees of £126 2*s*., towards which the guardians, with the sanction of the Local Government Board, had awarded gratuities amounting to £45; and whether, seeing that out of the 5398 births registered in the West Bromwich union in the year 1910, 1695 children have been legally exempted from vaccination, and in respect of 4463 births registered in the present year up to Oct. 31st, 1483 statutory declarations of conscientious objection had been received, he would consider the advisability of the vaccination officer's fees of 3*d*. per birth and 9*d*. per successful vaccination being revised for the work performed by him; and whether, having regard to the fact that the guardians had refused to increase the officer's fees and had intimated that they would not sanction any further gratuities although the officer was still suffering hardship from a continual increase of exemptions, he proposed to take any action to bring the officer's remuneration up to the average for the years 1903-07 or thereabouts.—Mr. BURNS answered: I am aware of the circumstances of the case. In sanctioning the gratuity proposed by the guardians in March last I drew the attention of the guardians to the losses suffered by the vaccination officer, and suggested an increase of fees. In April the guardians submitted a proposal to appoint the vaccination officer as assistant relieving officer at a salary of £1 per week; and one of the conditions attached to this appointment was that no further claim for loss of vaccination fees should be made by the vaccination officer. The vaccination officer, so I was informed, was quite satisfied with this arrangement, and I sanctioned the appointment. No further communication on the matter has been received from the vaccination officer.

Mr. BUTCHER: Might I ask the right honourable gentleman, in view of the difficulty of dealing with individual local authorities, whether he will issue a general order on the subject of the remuneration of vaccination officers?—Mr. BURNS answered: On that point I have very little to add to the communications I made to the honourable Member on previous occasions. We are dealing with the 25 outstanding grievances, and we are meeting with considerable success.

Mr. SNOWDEN asked the right honourable gentleman whether he had sanctioned the practice of paying fees to workhouse medical officers for vaccinations performed by them in Poor-law institutions; and, if not, whether he would issue an order directing that the performance of vaccinations should be regarded in future as part of the ordinary

duties of the officers for which they were paid by salary.—Mr. BURNS replied: I may refer the honourable gentleman to previous answers. The system of payment by fees which was established by Statute in 1867 has been continued since. I am, however, not unwilling to consider the question of allowing a workhouse medical officer an inclusive salary to cover payments for vaccination when a vacancy has to be filled.

Mr. SNOWDEN: Has the practice mentioned in the latter part of the answer been adopted in any case?—Mr. BURNS replied: Yes.

Mr. SNOWDEN asked the right honourable gentleman whether the vaccinations performed in Poor-law institutions were performed by public vaccinators only or by the workhouse medical officers when the latter were not public vaccinators; why these vaccinations could not all be performed by the medical officer to the workhouse, whether he was a public vaccinator or not; and why the salary paid to the workhouse medical officer could not include the cost of vaccinating the inmates.—Mr. BURNS said in reply: In most cases the workhouse is a separate vaccination district, and a contract has been entered into for the performance of vaccination in it with the medical officer of the workhouse. Where there is no such contract the workhouse medical officer is in nearly every case the public vaccinator of the district including the workhouse, and vaccinates in that capacity. It is not the duty of the workhouse medical officer as such to vaccinate any of the inmates of the workhouse other than the children requiring vaccination.

TUESDAY, DEC. 5TH.

Medical Men in Scattered Districts in Scotland.

Mr. AINSWORTH asked the Secretary to the Treasury whether the Local Health Committees in Scotland to be appointed under the National Insurance Bill would have the power to award additional remuneration to medical practitioners in sparsely populated districts on the basis of mileage or otherwise.—Mr. MCKINNON WOOD replied: Local Insurance Committees may, within the resources at their disposal, make such arrangements with medical men as they think fit, and the amount available for medical benefit may be increased either by the reduction of the other benefits which they administer, or where this is possible and the authorities concerned consent, by grants chargeable to the rates and to the Treasury in equal proportions.

Rutherfoord, to Mary Frances Caddy, daughter of John Francis Caddy, and granddaughter of Mrs. Caddy, of Charterhouse, Richmond, Surrey.

DEATHS.

COOPER.—On Dec. 1st, at the West London Hospital, Hammersmith, from blood poisoning contracted while assisting at an operation, Leonard Kingsford Cooper, L.R.C.P., M.R.C.S. Eng., Blackheath, S.E., aged 25 years.

WESTBY.—On Nov. 9th, at Beaufort West, Cape Colony, Ashley John, M.B., youngest son of the late Canon H. H. J. Westby.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE DANGER OF USING ELECTRICAL BED-WARMERS.

To the Editor of THE LANCET.

SIR,—It is with great regret and indignation that an electrical manufacturer reads of the facts "Cave" mentions in your issue of Nov. 18th—viz., that bed-clothes have been set on fire, and a lady nearly injured by the use of an electric bed-warmer. Now it is known, indeed, that there are various types of electric bed-warmers on the market which, from business and ethical reasons, should be condemned to non-existence. Nevertheless, they exist, as "Cave's" communication shows, and there are three causes which explain their existence—namely, (1) manufacturers without the knowledge of the simple mechanical and electrical principles at work in the electric cushion; (2) manufacturers who wish to earn more profit than is fair; and (3) manufacturers who wish to take every available order, and who must therefore manufacture cheaply and without sufficient care.

If these three considerations did not exist on the part of the manufacturers, or if the electrical device is made in accordance with Ohm's and Joule's law, &c., and if good material is worked in the hands of skilled and reliable mechanics, and the whole process kept under strict supervision and adequate testing—then there is not the shadow of a danger in using an electric bed-warmer.

If "Cave" will be kind enough to test the electric cushions made in my factory he will see the impossibility of their igniting, because as soon as the temperature in one part of the cushion reaches 210° F. one of the safety devices cuts off the current altogether. Of course, these safety devices must not only be there, but they must also work properly, and when the temperature has fallen the current is again switched on. It would be ridiculous to put a fuse into the cushion, which would be blown often enough and make the apparatus each time liable to repair.

All I can say is that my electric cushions are absolutely reliable, and having personally tested hundreds of them before sending them out of my factory I have never had a single complaint. On the other hand, as most of them have gone to hospitals and private patients they have proved a helpful addition to clinical means. My cushion is recognisable by the lead seal marked "H" on every one and the rotary switch regulator on the cord which regulates the temperature while in use.

I am, Sir, yours faithfully,

Berlin, Nov. 25th, 1911. RICHARD HEILBRUN, Ph.D., A.A.T.E.E.

WANTED, A POST.

To the Editor of THE LANCET.

SIR,—Would some of your readers kindly inform me as to the best method of getting a middle-aged maternity nurse (Queen Charlotte trained) attached to some institution where she would have a home to go when disengaged, and where she would be sure of getting the one thing she most desires—viz., work and a fair remuneration for the same?

I am, Sir, yours faithfully,

JOHN E. H. PARSONS.

The Cottage, Shipton-under-Wychwood, Oxford,
Dec. 4th, 1911.

RAGGED SCHOOL UNION AND SHAFTESBURY SOCIETY.

To the Editor of THE LANCET.

SIR,—There is nothing novel about the bitter need of the poorest children of London in the winter time; unfortunately it recurs with depressing regularity. And with it must be repeated, by your kind permission, my appeal to your readers for their generous help of the work of the Ragged School Union. This society has been the true friend of London's poorest children for nearly 70 years. Our work, while resting on a religious basis, is unsectarian and non-faddist, and by reason of our long experience we claim that it is economical and practical. We exist to meet promptly the real and pressing needs of the slum child. Our relief work can be summed up briefly as follows: Food for the child that is hungry; clothes for the child that is ragged; boots for the little feet blue with cold; simple pleasures for the sad, and healing for the sick and crippled. To all who are well fed, warmly clad, soundly shod, happy and healthy, I earnestly appeal on behalf of those unfortunate "opposites" down in the dark places of London's poor streets. A careful expenditure of all funds entrusted to the R.S.U. is guaranteed, and I can safely promise a wealth of gratitude for every penny your readers kindly send to me.—I am, Sir, yours faithfully,

JOHN KIRK, Director and Secretary.

32, John-street, Theobald's-road, London, W.C., Dec. 1st, 1911.

Quis (*M.D.*).—1. The workhouse infirmaries are supported out of the rates, and the patients are supported by the parishes or unions. 2. The county hospitals, not necessarily, but very generally, in or quite near to the county towns, are supported by voluntary subscriptions.

M.D. writes: I have a patient who suffers from a good deal of discomfort from underclothing. I should be obliged if any of your readers could inform me about any texture which is non-irritating and at the same time cool.

Service.—Is not the point rather that all practitioners enter the profession after long, difficult, and costly training, and in this respect all have an equal right to consideration?

Disgusted.—We are much obliged to our correspondent; and will see if we can make useful comment upon the speeches of the politician in question.

Staff.—Such attendance would certainly not be objected to.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for the next few months:—

Dec. 4th–9th (Havana, Cuba).—American Public Health Association.
" 12th–14th (Washington, D.C.).—Southern Surgical and Gynæcological Association.
" 19th–23rd (Moscow).—Third Pan-Russian Therapeutical Congress.
" 27th–30th (Baltimore).—American Physiological Society.

In 1912:—
Jan. 20th–27th (Hong-Kong).—Second Biennial Congress of the Far Eastern Association of Tropical Medicine.
Feb. 13th–14th (London).—Central Poor-Law Conference.
March 7th–11th (Berlin).—Thirty-third Balneological Congress.
" 23rd–April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.
" (London).—First Congress of Pure Food and Health Society of Great Britain.
April 1st–7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.
" 14th–20th (Rome).—Seventh International Congress on Tuberculosis.
" (Rome).—Seventh International Congress of Dermatology and Syphilology.
" (Giessen).—Congress on Study of Families, Inheritance, and Race Hygiene.
Spring (London).—Second Optical Convention.
May 7th–17th (Washington).—Ninth International Red Cross Conference.
" 27th–June 1st (London).—Eighteenth International Congress of Americanists.
" (London).—International Horticultural Exhibition.
June 24th–27th (London).—The (Biennial) Health Conference and Exhibition.
" (London).—Missionary Exhibition.
" (Dublin).—Celebration of the Bicentenary of the School of Physic in Ireland (Medical School of Trinity College, Dublin).
July 2nd–5th (London).—Congress of the Universities of the Empire.
" 2nd–6th (Doncaster).—Seventy-third Annual Show of the Royal Agricultural Society of England.
" 12th–16th (London).—Imperial Conference of Teachers' Associations.

METEOROLOGICAL READINGS.

The following journals, magazines, &c., have been received:—
Journal of the Scottish Meteorological Society, Polyclinic, Man, Medical Chronicle, Yellow Fever Bureau Bulletin, Public Health, La Clinique Infantile, Transactions of the American Otological Society, Revista Stiintelor Medicale, Edinburgh Medical Journal, South African Medical Record, Dublin Journal of Medical Science, Transvaal Medical Journal, Practitioner, Indian Medical Gazette, Indian Medical Journal, Medico-Surgical Journal of the Tropics, Annales de Gynécologie et d'Obstétrique, Journal of the Royal Sanitary Institute, Montreal Pharmaceutical Journal, Canadian Journal of Medicine and Surgery, Cleveland Medical Journal.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W (temporary address during building of new house).

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—L. A. Dunn, James Berry): at 5.30 P.M.

Short Papers:

The President (Mr. Clinton T. Dent): Case of Intestinal Obstruction following an Ovariotomy 45 Years Previously.

Mr. Robert Jones (Liverpool): Treatment of Claw Foot.

Mr. Thomas H. Kellock: The Results of the Operation for Inguinal Hernia in Young Children.

Mr. John Murray: Case of Pancreatic Calculus—Stone Removed by Operation.

Mr. Walter G. Spencer: Hydrocephalus Internus—Subdural Rupture causing Hydrocephalus Externus.

WEDNESDAY.

BALNEOLOGICAL AND CLIMATOLOGICAL SECTION (Hon. Secretaries—A. Manuel, F. A. de T. Mouillot): at 5.30 P.M.

Paper:

Dr. G. Monod (Vichy): The Treatment of Gastro-hepatic Dyspepsia at Vichy, Carlsbad, and Cheltenham.

(At 7 P.M. the Members will dine together at Bellini's Restaurant, Mill-street, Regent-street, W. The charge for the dinner is 4*s.* 6*d.*, and Members may bring their friends. Dr. Manuel will be glad to receive names of those intending to dine.)

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—J. H. Sequeira, Wilfred Fox), at 11, Chandos-street, W.: at 5 P.M.

Demonstration of Cases.

NEUROLOGICAL SECTION (Hon. Secretaries—Wilfred Harris, T. Grainger Stewart): at 8 P.M.

Clinical Meeting:

Dr. Garrod: Case of Myotonus.

Dr. James Collier: (1) Peculiar Case of Congenital Paralysis; (2) Three Cases of Bilateral Athetosis.

Mr. Percy Sargent: Three Cases of Facial Palsy treated by Hypoglossal Anastomosis.

Dr. Otto May: (1) Case of Cerebral Diplegia treated by Posterior Root Section; (2) Case of Cerebral Monoplegia.

Dr. P. W. Saunders: Pituitary Tumour with Hypopituitarism.

Cases

Will also be shown by Dr. James Taylor, Dr. Leonard Guthrie, Dr. Hinds Howell, and others.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—T. R. Whipham, H. S. Clogg, Percy G. Lewis), at 11, Chandos-street, W.: at 4.30 P.M.

Discussion

On the Treatment of Tuberculous Joint Disease in Children, to be opened by

Mr. A. H. Tubby: The Relative Advantages of Operative Measures.

Sir Anthony Bowlby, C.M.G.: The Results Obtainable without Operation.

Dr. A. Butler Harris: The Rôle of Vaccine Therapy.

The following also will take part in the Discussion: Mr. A. E. Barker, Sir W. Watson Cheyne, C.B., F.R.S., Mr. Robert Jones (Liverpool), Mr. J. Jackson Clarke, Mr. R. M. Corner, Mr. P. Lockhart Mummery, Mr. W. G. Sutcliffe (Margate), Mr. H. J. Gauvain (Alton), Mr. R. C. Elmslie.

ELECTRO-THERAPEUTICAL SECTION (Hon. Secretaries—G. Harrison Orton, Cecil R. C. Lyster): at 8.30 P.M.

Clinical Meeting:

Interesting Skiagrams, &c., will be shown by Dr. Aldridge, Dr. Ironside Bruce, Dr. Lewis Jones, Dr. Reginald Morton, Mr. A. D. Reid, Mr. Gilbert Scott, and others.

Demonstration of the "Oscillothermex," a combined apparatus for Diathermy, High Frequency, and X Ray Treatments.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Mr. J. D. Malcolm: Some Remarks on 400 Operations involving the Peritoneum and a Comparison of the Fatal Cases, 3·75 per cent., with those of the Writer's Earliest Work.

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Grosvenor-road, S.W.

WEDNESDAY.—5 P.M., Fleet-Surgeon D. J. P. McNabb: Hospital Ships and their Functions.

OPHTHALMOLOGICAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

THURSDAY.—8 P.M., Card Specimen will be shown by Dr. Edridge-Green, Mr. A. H. Levy, Mr. W. H. McMullen, Mr. A. S. Worton, and Mr. N. B. Harman. Papers:—Dr. T. Henderson: The Pathogenesis of Choked Disc.—Dr. A. Bronner: Notes on Three Cases of Ulcer of the Cornea combined with Painful Spasm of the Sphincter Pupillæ.—Mr. J. H. Parsons and Mr. E. K. Martin: The Action of Ultra-Violet Rays upon the Ciliary Body and Lens.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, 17, Bloomsbury-square, W.C.

TUESDAY.—8 P.M., Prof. H. G. Greenish: A Series of Slides Illustrating Caraway Cultivation in Holland. Mr. G. C. Druce: A Visit to Japan (illustrated by lantern slides).

NEW LONDON DERMATOLOGICAL SOCIETY, 20, Hanover-square, W.

THURSDAY.—4.30 P.M., Clinical Cases.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. H. G. Adamson: Clinique (Skin). 5.15 P.M., Lecture:—Dr. U. Pritchard: Complication of Middle Ear Suppuration.

TUESDAY.—4 P.M., Dr. J. J. Perkins: Clinique (Medical). 5.15 P.M., Lecture:—Dr. A. J. Jex-Blake: Congenital Heart Disease.

WEDNESDAY.—4 P.M., Mr. P. Turner: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. R. A. Gibbons: Pruritus of the Vulva.

THURSDAY.—4 P.M., Mr. R. J. Howard: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. T. Claye-Shaw: The Mode of Thought in the Insane.

FRIDAY.—4 P.M., Dr. J. D. Grant: Clinique (Ear, Nose and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. Dr. Simson: Diseases of Women. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. P. Dunn: Glaucoma.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Morton: X Ray Diagnosis.

WEDNESDAY.—10 A.M., Dr. Simson: Gynæcological Demonstration. Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M.. Dr. Simson: Diseases of Women. 5 P.M.. Lecture:—Mr. Bidwell: The Treatment of Acute General Peritonitis.

THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery. (Lecture VI.)

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M.. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. S. Taylor: A Trace of Albumen.

SATURDAY.—10 A.M., Medical Registrar: Demonstration of Cases in Wards. Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. Bishop Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 3.15 P.M., Special Lecture:—Sir Dyce Duckworth: The Personal Factor in Disease.

TUESDAY.—2 P.M., Operations. 3.15 P.M., Dr. R. Wells: Medicine. 2.15 P.M., Mr. R. Carling: Surgery. 4.15 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 4.30 P.M., Special Lecture:—Prof. Hewlett: Recent Researches on the Function of the Hypophysis Cerebri.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 2.15 P.M., Special Lecture:—Dr. F. Taylor: Pain in the Back.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Sir J. Rose Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—10 A.M., Radiography. 11 A.M., Dr. A. Davies: Pathological Demonstration. 2 P.M., Operations. Out-patient Demonstration:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. D. Gillies). 3 P.M., Pathological Demonstration (Dr. Duncan).

TUESDAY.—Clinic; 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld).; Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Lecture:—Dr. R. M. Leslie: The Tuberculin Treatment of Tuberculosis.

WEDNESDAY.—**Clinics:**—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Mr. W. Steuart); Pathological Demonstration (Dr. Duncan). 5.30 P.M., Eye Operations (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. B. Giles). **Clinics:**—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel). 4.30 P.M., **Lecture:**—Dr. G. G. Macdonald: The Natural Cure of Diseases.

FRIDAY.—2.30 P.M., Operations. **Clinics:**—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie); Pathological Demonstration (Dr. Duncan).

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., **Lecture:**—Dr. Maguire: The Germicide Treatment of Pulmonary Tuberculosis.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. F. Batten: Paraplegia.
FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. G. Holmes: Cerebellar Disease.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY AND FRIDAY.—3.45 P.M., Lecture:—Mr. A. Wylie: Larynx.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Dr. W. Griffith: Pathology of the Dermis.
THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Bullous and Vesicular Eruptions (continued)—V., Herpes; VI., Zoster; VII., Dermatitis Herpetiformis.

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Mr. W. R. Douglas: Chronic Enlargements of the Testicle. (Post-Graduate Clinic.)

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (11th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (12th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (13th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's 2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (14th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (15th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)., Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (16th).—Royal Free (9A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from—

A.—Dr. R. J. Anderson, Galway; Messrs. Armour and Co., Lond.; A. M. T. M.; Australian Institute of Tropical Medicine, Townsville, North Queensland; Dr. H. J. Achond, Chicago; Aberaychan and District Workmen's Medical Fund, Secretary of; Anglo-American Pharmaceutical Co., Croydon; Messrs. Arnold and Sons, Lond.; Messrs. E. G. Allen and Son, Lond.; Ardath Tobacco Co., Lond.; Army and Navy Male Nurses' Co-operation, Lond., Hon. Secretary of.

B.—Mr. L. A. Bidwell, Lond.; Beckett Hospital, Barnsley, Secretary of; Birkenhead Borough Hospital, Secretary of; Messrs. Boulton and Paul, Norwich; Messrs. Burroughs, Wellcome, and Co., Lond.; Benger's Food, Manchester; British Medical Benevolent Fund, Lond., Hon. Secretary of; Dr. C. Hubert Bond, Epsom; Dr. H. Charlton Bastian, Lond.; Sir H. T. Butlin, Bart., Lond.; Messrs. C. Barker and Sons, Lond.; Mr. H. Burrell, Burton-on-Trent; Sir Lauder Brunton, Bart., Lond.; Mr. Frank Bryan, Lond.; Dr. G. Blacker, Lond.; Mr. O. Berthier, Paris; Birmingham and Midland Hospital, Secretary of; Blackburn and East Lancashire Infirmary, Secretary of; Dr. John B. Berry, Keighley; Dr. A. G. Bateman, Lond.; British Fire Prevention Committee, Lond., Assistant Secretary of.

C.—Mr. H. A. Collins, Croydon; Messrs. E. Cook and Co., Lond.; Messrs. Cassell and Co., Lond.; Messrs. Corbyn, Stacey, and Co., Lond.; Dr. D. Campbell, Digboi; Messrs. A. Clarkson and Co., Lond.; Dr. H. J. Cardale, Lond.; Mr. G. H. Colt, Aberdeen; Dr. H. P. Cholmeley, Westerham; Dr. E. Clarke-Jones, Lond.; Dr. J. D. Chepmell, Worthing; Dr. Harry Campbell, Lond.; Dr. Maurice A. Cassidy, Lond.; C. R. G.; Dr. R. T. Cæsar, Maidstone; Cunard Steamship Co., Liverpool; Messrs. Samson Clark and Co., Lond.; Messrs. The Hunterian Lecture
ON
THE INTRA-ABDOMINO-PELVIC PRESSURE IN MAN.

Delivered before the Royal College of Surgeons of England on Nov. 17th, 1911,

BY R. H. PARAMORE, M.D. LOND., F.R.C.S. ENG.,

PATHOLOGIST AND REGISTRAR, HOSPITAL FOR WOMEN, SOHO SQUARE.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—Last year, in my lectures on the Evolution of the Pelvic Floor,[20] I referred that process to the necessity for a pressure within the body cavity which as evolution proceeded became more and more important.

RELATIONSHIP BETWEEN VISCERAL PRESSURE AND METABOLISM.

This conclusion was based on the association that step by step with the advance in structure a corresponding increase in dominance over the environment obtained; the two changes, the one in structure, the other in activity, running along such parallel lines, and the association being of such an intimate nature as to have a causal relationship. On the one hand, we saw that as the abdominal wall began to be differentiated the first indication of a pelvic floor appeared; that as the abdominal wall further evolved a similar advance in the pelvic floor was found; and that still more marked changes occurred in it with the appearance of the thoracic diaphragm: from which it was clear the development of these three musculatures was correlated, mutually dependent on a common cause, which itself increased in intensity from stage to stage. And, on the other hand, an analysis of the progressive change in the habits and conditions of life, exhibited by members of this series, revealed this cause to be a progressively increasing demand for a more and more effective internal pressure. For I showed how the medium in which the animal lives must influence the pressure within the body cavity, of which even in the fish an increase was necessary for visceral acts; that to obtain the same effect as before, the same return of blood from the viscera to the heart, the body wall of air-dwelling vertebrates had to be more active than that of water-dwelling vertebrates; that with the advent of ribs the excursions of pressure had to be greater than in animals without a thorax, since the greater quantity of air inspired necessitated an amplified expiration; and that with the establishment of mammals, characterised by a still greater increase in activity, still greater excursions had to occur. Throughout the series we have a progressively heightening metabolism of the organism as a whole, called forth by the necessity for greater activities, exemplified at each stage, demonstrating once and for all the intimate relationship between the visceral pressure and general metabolism.

SOME OF THE PROBLEMS TO BE CONSIDERED.

It is plain if this generalisation be true—if an adequate internal pressure has been and still is of such importance in the lower vertebrates that their respective positions in nature have only been reached and maintained by the adaptation of the muscles enclosing their viscera in each class for such an end—we ought to find in man a similar and a correspondingly advanced association; correlated with his remarkable predominance, the musculatures enclosing his viscera should be the best developed of all the vertebrates; and arguing from analogy, their purpose should be the production of an intensified internal pressure. If so, we should find evidence that the pressure is not merely a passive result of visceral weight as some have supposed [9 15 17 25] or caused indirectly by the muscular contraction maintaining the body in equilibrium, as others have thought,[23] but that it is produced for a purpose of its own, which reacts on the body as a whole; and inversely, that when this complicated muscular mechanism becomes defective in one or other direction, producing an average pressure too high or too low, a general bodily effect ensues; we ought to discover with the resulting pressure change deviations from the normal, pathological states, dependent on its rise or occurring with its fall.[24]

Such are the problems involved in a consideration of the intra-abdomino-pelvic pressure in man. To-day, it is impossible to treat the subject with completeness; time only permits some fundamental points may be touched on; but especially do I wish to show that besides the very considerable pressure caused by activity and straining—to which the term "intra-abdominal pressure" is so often limited—even during posture and rest, a pressure is maintained within the abdomen; and next, that during activity and all active postures, this pressure is due mainly or even entirely to the contraction of the muscles enclosing the viscera, which even during recumbency participate in its production, and so that the visceral weight is correspondingly negligible; and finally, to refer briefly to the physiological significance of this pressure.

HIGH DEVELOPMENT OF THE ENCLOSING MUSCULATURES IN MAN.

We may first notice man indeed falls within the generalisation referred to; for a comparison of the three enclosing musculatures in terrestrial pronograde mammals with those in him shows that the maximal advance in development has been reached in the human type. The pelvic floor musculature, instead of enclosing a very narrow wedge-shaped space, as in carnivora—in which most probably of all pronograde mammals the greatest excursions of visceral pressure occur—presents in man as a wide slightly concave sheet, forming a true floor, a real supporting structure, its upper surface opposing more or less at right angles the down-thrust of the viscera, and therefore being more capable of resisting a longer sustained and a more direct—i.e., a greater—pressure from above than occurs or can occur in the former animals. The abdominal wall and thoracic diaphragm show corresponding advances. In the former, the transversales, size for size, are much thicker and stronger; Professor Keith[11] has shown that with the assumption of the upright carriage the muscle has gained about one-third in weight. And the diaphragm is not only better developed, but its attachments pass much more deeply into the abdomen,* so that we have, according to the same observer,[11] two distinct types of this muscle—one found in animals which go on all fours, and one peculiar to animals that walk erect. This greater development of the transversales and of the diaphragm in orthograde mammals cannot have been required to maintain the body in equilibrium when erect by a direct action on skeletal parts; nor can it be supposed that the advance in the diaphragm has been caused by a change in the elasticity of the lungs.

FUNCTION OF THE ENCLOSING MUSCULATURES.

What can the function of these extensive musculatures be if not to contract upon the collective viscera in the abdomen and by compressing them to cause a pressure effect? Let us briefly consider their action. The two transversales with their intermediate tendon form a continuous sheet, closely applied at the front and at the sides to the visceral mass, their fibres passing for the most part horizontally from one side to the other. Since the lumbar and pelvic fibres, when they contract, cannot in any way cause an approximation of their skeletal attachments, the resulting effect must be a compression of the viscera to which they are apposed, tending to displace the lower ones into the pelvis, causing a pressure there, and simultaneously preventing a descent of the epigastric viscera. Contraction of the epigastric fibres, however, which arise from the margin of the costal arch on each side, may cause a narrowing of this arch and a diminution in volume of the thoracic base, and a consequent displacement of the epigastric viscera and with them of the diaphragm upwards into the chest; but if the diaphragm prevent this upward displacement, a narrowing of the thoracic base will not occur, but the pressure therein will be maintained raised.

That such an effect will occur when the transversales contract will be readily granted; for instance, during straining and laughing and similar acts, no one will dispute that a considerable visceral pressure occurs in which the transversales participate. But the question to be considered is, when do these muscles not contract, when is their relaxation complete? I cannot to-day attempt to answer this question. I can only remind you that even during apparent rest the

* The diaphragm is better developed in aquatic mammals than in man; this is due to the density of the water in which they pass so much of their time, and does not vitiate the argument.

fibres of striated muscle are in a state of partial contraction or tone (Pembrey [21]), which determines a pull on their skeletal attachments. If this be admitted, it is clear, provided the diaphragm simultaneously exerts a pressure downwards, that even during rest a visceral pressure exists. We must remember the transversales are well-developed muscles, and consequently play some considerable part in the economy of the body, for if they did not function their regression would occur. That their purpose is to cause a pressure effect is indeed indicated by their phylogeny; for they first appeared in the amphibia, just in those vertebrates, that is, for which a terrestrial life with all its possibilities began, and for which the emergence from the denser medium of water to the much lighter one of air was a definite accomplishment.

That the thoracic diaphragm is similarly concerned with causing a pressure effect within the abdomen, by tending to thrust the epigastric viscera downwards, is indicated by the high position of its trefoil tendon, the steep descent of its costal fibres, and the remarkable length and muscular development of its crura, which reach far into the abdomen—as low as the second and the third and even the fourth lumbar vertebræ: just the very anatomical conditions, in conjunction with those of the abdominal wall, by which a pressure effect within the abdomen could be most easily produced. And were it not that the diaphragm separates the abdomen from the thorax, and is as closely related to the lower thoracic viscera as it is to the upper abdominal, no one would doubt it to be a compressor of the latter and that it is an abdominal muscle.

THE DIAPHRAGM AND NEGATIVE PRESSURE IN THE CHEST.

But the negative pressure within the chest introduces a difficulty: for continuously exerting an aspiratory effect on the diaphragm, it has been thought to have drawn the diaphragm upwards and to be the cause of its high position; and for this reason, and because the diaphragm participates in inspiration, it has been assumed to be a purely respiratory muscle, that it exists only to overcome the elasticity of the lungs, and that, except when violently contracted as by straining, it does not compress the abdominal viscera. In line with this conception, it has been supposed the epigastric viscera are maintained in position, suspended, by the negative pressure within the thorax, and that in the erect posture, since they tend to gravitate downwards and to drag the diaphragm with them, they not only aid the diaphragm in overcoming the elasticity of the lungs, but cause a partial vacuum in the epigastrium—that is, that the pressure there is negative. It has even been thought, both formerly and recently, that the adhesion of the pericardium to the diaphragm below, and its attachment to the fascia of the superior mediastinum, and so to that of the neck above, forms one of the chief supports of the diaphragm and plays a part in the support of the abdominal viscera. The Roentgen rays, however, demonstrate that descent of the central tendon occurs (Keith); so it is clear this mediastinal fascia, which does not prevent such descent, cannot be the cause of the high position of the epigastric viscera. These epigastric viscera, moreover, extend a little higher into the chest laterally in the regions of the cupolæ than centrally in the region of the attachment of the pericardium, and, what is more remarkable, the heavy right lobe of the liver reaches a little higher than the stomach in the left hypochondrium.

ACTION OF THE DIAPHRAGM.

At first sight, the negative pressure in the thorax may appear sufficient to explain the high position of the epigastric viscera, just as Matthews Duncan [3] supposed the thorax expanded, and Schatz [23] stated the intercostal muscles hypertrophied, in pregnancy to help bear the heavy uterus by an increased suction upwards. And, in the same way, the mere weight of the epigastric viscera may appear sufficient to explain the descent which occurs on change from the supine to the erect posture. But this hypothesis takes no account of the structural condition of the diaphragm. Much more likely is it that the descent of the epigastric viscera, which occurs on rising to the erect from the supine posture, is caused to a large extent at least, if not mainly or entirely, by the diaphragm actively depressing them, or rather rotating them, downwards and forwards, a movement which determines the enlargement of the thoracic base, and results in an increase in the vertical diameter of the chest. By this enlargement of the thorax and change in the abdomen the pressure within each is so altered that the difference between them becomes greater; indeed, the pressure within the epigastrium, as measured within the stomach, is, according to Moritz, absolutely increased. Thus, more blood is squeezed into the thorax towards the heart, so that the aortic pressure may be raised on standing and the cerebral circulation safeguarded in this otherwise dangerous position. Such action of the diaphragm could only be rendered effective by the abdominal wall resisting the descent of the epigastric viscera; and this opposition affords an adequate explanation of the structural development of the diaphragm, and at the same time indicates that the position of the epigastric viscera is dependent upon the reaction between these two musculatures.

For it is unlikely the diaphragm would be so well developed were it a purely respiratory muscle, and had only to overcome the elasticity of the lungs, because the force this elasticity exerts is comparatively small. If this were all we should expect the diaphragm in man, instead of being better developed than in the terrestrial pronograde mammals, to be no better developed; and if in man the weight of the viscera really assists the diaphragm, it ought not to be even as well-developed as in these lower mammals. Further, we should expect expiration to be a physical elastic recoil permitted by relaxation of the diaphragm, but due to shrinkage of the lungs, instead of being effected, governed, and controlled by muscular action as Professor Keith has pointed out that it is.[12] Indeed, we find the negative pressure in the thorax is not suddenly produced at birth, but develops slowly—is, indeed, not demonstrable during the first four days of life, and at the eighth day of life, according to Hermann,[6] is only −0·4 mm. Hg, so that in the first few days of life the elasticity of the lungs does not come into play for expiration, yet expiration occurs, and it can only be produced by a muscular contraction of the body wall muscles.

At this time the act must be comparatively difficult; and, like so many other phenomena in the early life of man, represents in this feature, more or less, the conditions which prevailed during the early evolution of the vertebrates, when expiration, first attempted, became established—an accomplishment effected by the development of the external oblique muscles of the body wall, which evolved to meet and overcome this at first seemingly insuperable difficulty. The increase in elasticity of the lungs has rendered the act easy in adult man; but the ease of its accomplishment is a spurious reason for the argument that expiration is a passive recoil, and that muscular activity does not determine it; for many contractions of muscle occur and continue of which we are unconscious—such, for instance, as that of the transversales during rest. But, even in the adult, the apparently passive expiration has a limit, beyond which expiration can only be continued by a forcible contraction of the body wall muscles, in spite of the fact that the lungs are still elastic and a negative pressure still persists in the thorax, as it does even after the most forcible expiration. This forcible contraction of the body wall muscles has to be made even in the supine position, when the weight of the epigastric viscera, in so far from hindering, may even facilitate it; it is, indeed, easier to effect in the erect posture than when lying down, probably because the volume of the thorax is larger in the former position and the difference of pressure within it and the abdomen greater; clearly, it is produced to overcome the resistance of the still contracted diaphragm, for there is no other structure than the diaphragm to occasion it.

From this it seems reasonable to infer that the continued contraction of the abdominal wall in ordinary expiration is required, not because the lungs are unable to shrink without it, but because the diaphragm opposes the act—opposing it, not violently, but gently, therefore expiration is easy; but opposing it with a force which is greater, not less, than the force of the elastic recoil of the lungs, for the reason that the pressure in the abdomen must remain ever greater than that in the thorax. Thus, in the abdominal type of breathing expiration is effected by the abdominal wall actively pushing up the epigastric viscera, and with them the diaphragm, in spite of its continued contraction, by which means a pressure in the abdomen greater than in the thorax is assured. That the diaphragm continues to exert a pressure downwards during ordinary expiration is shown at once by the fact that the pressure in the stomach does not become negative or reach zero during ordinary expiration,[13] as we should expect

it to do if the diaphragm became flaccid and allowed an equalisation of the very different pressures on its opposite sides to occur.

CONTINUOUS DOWNWARD PRESSURE OF DIAPHRAGM.

That the diaphragm, by its contraction, usually exerts a pressure downwards upon the epigastric viscera is clear from these considerations; that it usually does so when it violently contracts no one will deny. But the question again arises, When does the muscle not contract? The necessity for a continued activity of the abdominal wall muscles during expiration, when we should expect the diaphragm to relax, shows that the elasticity of the lungs is insufficient to overcome the diaphragm even when partially inhibited. From my study of this subject I have come to the opinion that the diaphragm only becomes completely relaxed—that is, flaccid—exerting no traction downwards on the thoracic side, and no pressure downwards on the abdominal—when the pressure in the thorax becomes raised and equals that in the abdomen, as may occur when straining movements are made with the glottis closed. This is exemplified by the act of coughing. In this act, after a breath has been taken, the glottis is closed and the pressure in the thorax considerably raised by an increased contraction of its muscles; the glottis is then opened, and a blast of air escapes. The escape, however, is peculiar in this, that it is not sustained; moreover, not only is the outrush of air suddenly checked, but a great and rapid rise of pressure in the abdomen is produced, which is propagated downwards throughout its cavity, bulging the hypogastrium and being transmitted into the pelvis. This, it seems to me, is determined by a sudden contraction of the diaphragm, the stimulus for which is the sudden lengthening of its fibres, made possible by a state of relaxation and caused by the rapid fall of pressure in the thorax. At all other times the diaphragm is contracted, even during expiration, and the force it exerts downwards is not only sufficient to overcome the elasticity of the lungs when these can distend, but to cause a compression of the abdominal viscera which it is able to do, provided they be of sufficient bulk, in virtue of the resistance offered by the abdominal wall.

For it is to be noticed that if by expanding the thorax the lungs be distended to their utmost so that they can stretch no more, or if they be prevented from distending by a closure of the glottis which can be voluntarily produced, however much the diaphragm contract, it will not be able to descend. Under these circumstances, if the spine be extended, the pressure in the epigastrium may easily become negative, epecially in thin individuals, in spite of a continued contraction of the enclosing muscles. The enlargement of the thorax causes an advance of the sternum, and this with extension of the spine causes the abdominal wall to become recurved, unless the volume of the viscera be unduly large. The resulting negative pressure may be due in part to the tendency of the epigastric viscera to sag downwards; but more probably the powerful recti muscles, which have a considerable width in the region of their thoracic attachments, play a greater part in the production of this negative pressure at least when it is marked. For instead of being bulged forwards, or running from the thorax to the pubes in a straight line, they are drawn inwards towards the spine by the transversales; and instead of adding to, or not affecting, the internal pressure, by tending to advance and to enlarge the abdominal cavity, they diminish the pressure. Thus, Professor Keith distinctly states that by taking a deep thoracic breath *and holding the abdominal walls as rigid as possible* he was able to produce a negative pressure of −4 mm. Hg in the stomach.[13] By such maximal inspiration the pressure in the chest, which at the end of ordinary inspiration equals about −7·5 mm. Hg (Howell)[10], sinks to about −30 mm. Hg or more (Howell)[10], so that even here we have a relatively much greater pressure in the epigastrium. It is obvious that a similar and greater negative pressure can be produced by expanding the thorax with the glottis closed, when the lungs are only partially distended, as after an expiration.[17] In this case, since air cannot enter the lungs, the diaphragm is forced to ascend in spite of its contraction, and a considerable enlargement of the thoracic base occurs into which the epigastric viscera pass, the abdominal wall being markedly drawn inwards. These conditions, however, are uncommon events in the body, the former occurring during yawning, the latter perhaps in the initial stage of vomiting; so that for practical purposes we may say the diaphragm is continuously exerting a pressure downwards upon the epigastric and other abdominal viscera.

The combined effect of the abdominal wall and thoracic diaphragm is thus to cause a general compression of the abdominal viscera. These, we find, have definite shapes, even the hollow intestinal tract, as sections of the frozen body show, and the more solid organs facets on their surfaces—clear evidence of how they all are compressed against each other and the enclosing walls during life, demonstrating, too, how by opposing each other and these walls they are maintained in place and are not suspended in the normal by any ligament. The pressure so caused in the large and extensive abdomen is propagated to the pelvis, which in its phylogeny, and indeed ontogeny, has reacted by an adaptation of its structure to successfully withstand it. We have already referred to the change in its floor. The shape of its cavity has also altered in that it has approached the form of a hemisphere—i.e., the form of greatest possible capacity with smallest superficies, a feature which distinguishes it from the pelves of all other animals, and is an indication in itself that a pressure continuously existed within it during life.

MANIFESTATIONS OF THE INTRA-ABDOMINO-PELVIC PRESSURE.

I pass on now to the manifestations and measurement of this pressure in man, and to a brief examination of the values found which may be expected to throw light on the mechanism of its production and to verify or disprove our tentative conclusions.

At the outset it is to be remarked that no evidence of a pressure caused by the tone of the abdominal wall and thoracic diaphragm can appear when these muscles are rendered more or less inactive as by general anæsthesia. The fact that on laparotomy in a well anæsthetised subject the intestines do not bulge out through the wound, nor air rush into the peritoneal sac, is no proof that during conscious life a pressure due to such muscular activity does not exist within the abdomen; and yet this observation appears to have caused doubt or denial of such pressure.

And experiments which put out of court this muscular activity are similarly void; such, for example, as those of Quirin,[22] who found immediately under the abdominal wall in anæsthetised animals a pressure which varied from 0 to 13 mm. of water;† and those of Hörmann,[9] who killed his animals outright, and then discovered that immediately beneath the abdominal wall no positive pressure existed. Nor do the experiments of Kelling,[15] who found in starving dogs which were not anæsthetised that the pressure within the abdomen immediately beneath the anterior abdominal wall in the dorsal decubitus was nothing (0), negative a tone of the abdominal walls in the normal dog, much less in normal man; for it is plain that the volume of the viscera plays a part in the pressure effect caused by the activity of the enclosing muscles, that the muscles will more easily cause a pressure when the visceral mass is large than when it is small. Reference has already been made to the occurrence of a negative pressure in the epigastrium of man, when the chest is maximally expanded and the spine hyperextended; this negative pressure is not due to an absence of tone of the abdominal wall, but to the action of the recurved recti muscles, which tend to pull the linea alba forwards and so to enlarge the abdominal cavity and thus to obstruct the action of the transversales which is to diminish it, and as a consequence the pressure within falls. So in starving dogs, in which the visceral mass is rendered small, it is not surprising that no positive pressure should obtain; for the depth of the epigastrium, i.e., the distance from the xiphoid process of the sternum to the spine, is very considerable in dogs, and the course of the recti highly arched. Moreover, the tone of the muscle itself cannot be so good in animals reduced by starvation; nutrition, clearly, is a factor in this question.

Nor must we be deluded into denying the existence of this pressure, because usually we are unconscious of it. Whilst we may recognise that a pressure change occurs within the abdomen during the straining associated with visceral acts, the fact that we are unconscious of a similar, though much smaller pressure when the body is maintained in various postures and during rest is, of course, no proof that such

† Contrast this with Lewis,[16] "The average pressure in the abdomen of 10 anæsthetised cats, lying on the back with the limbs gently fixed, was 2 mm. Hg." (Ibid., p. 242.)

pressure does not exist. Indeed, we are unconscious of the pressure in the abdomen when it is very considerably raised, as occurs during active movements, even violent ones, when the pressure may be greater than that associated with the straining for visceral acts; this, as Schwerdt[24] naively remarks, is because at such times we think of other things.

MEASUREMENT OF THE INTERNAL PRESSURE.

It is easy to convince oneself that a considerable pressure within the abdomen is produced by straining: the impulses caused by cough afford a ready example. But to show the existence of a pressure during rest and posture, it is necessary to use a manometer and to connect it by means of a tube with the interior of some viscus such as the rectum or stomach. It is best to fix a small bag, such as an ordinary thin rubber finger-stall, on to the end of the tube; this prevents the contents of the viscus from entering the tube and vitiating results. The bag is partially distended with air, so that whilst pressure changes may be transmitted to the manometer, the elasticity of the bag itself plays no part in their production; the bag is then passed; or it may be passed first, and then a known small amount of air pumped into it. It is necessary to see that there is free play of pressure between the bag and the manometer, by getting the patient to cough: if the mercury does not respond immediately, the bag must be readjusted, as kinking sometimes occurs. When this is done, if the subject is caused to assume different postures, different pressure-values are found, which for the same posture are always approximately the same.

Thus, in the case of the rectum, one finds in the left lateral position, the subject lying at ease, a positive pressure of 6 to 8 mm. Hg. On turning more on to the face and assuming the semi-prone position, the mercury is seen to fall and may reach zero, or a small negative pressure may be found; whilst, when lying flat on the back, but still at ease, the mercury rises and the rectal pressure is found to be considerably higher than when on the side. If the patient be now asked to get into the knee-chest position, a negative pressure of −6 to −8 mm. Hg will be found to occur; but to obtain this the thighs must be vertical, the chest low on the couch, and the back well arched so that it forms a marked concavity; otherwise a decided positive pressure may still persist. On standing erect an intra-rectal pressure of 20 to 28 mm. Hg is registered. On asking the subject to bend forwards whilst still standing, so that the body becomes horizontal, a fall of pressure to 10 to 18 mm. Hg occurs, rising again when the patient stands upright—this without corsets.

Effects of Movements.

If the manometer be watched as the subject changes from one position to another, elevations of pressure, at times quite considerable, will be noticed to occur; these are, of course, due to the active process of moving. As the required attitude is attained the mercury falls and becomes fairly stationary; often, however, subsequently falling a little more as the position becomes easy and the subject's attention is directed away from herself, the muscles then relaxing as much as they will. Even under such circumstances small oscillations, rhythmic in character, frequently occur, and are due to respiratory movements.

The effect of more violent movements upon the internal pressure can be studied by asking the patient to overcome external resistances. Thus, if whilst she is bending forwards she lifts a fairly heavy weight, a considerable increase of pressure results; according to my observations the pressure rises to 46 to 64 mm. Hg. It may, however, be much higher, reaching 120 mm. Hg (Keith). The effect of straining can be gauged by asking the patient to bear down when in the left lateral position. The mercury rises as a rule slowly, registering a pressure of 52 to 72 mm. Hg or even higher; and it remains raised and fairly stationary as long as the breath continues to be held and the straining effort is prolonged; on releasing the breath the mercury falls to its original position. The increase of intra-abdomino-pelvic pressure incident to straining is therefore characterised by its gradual rise and its sustained elevation. On coughing, the mercury shoots up to 80 or 100 mm. or more; but it falls as rapidly: the act causes but a momentary impulse.

Pressure-Values in the Epigastrium.

Coming now to the pressure-values in the epigastrium, it is established beyond doubt, by the work of Schwerdt,[24] Kelling,[15] Moritz,[17] and Keith,[13] that the pressure in the stomach in the normal—with the single exception already referred to—is always positive, even in the erect posture. Professor Keith, in his article on visceroptosis, puts it down from 4 to 8 mm. Hg during expiration, rising to 12 mm. Hg during inspiration.[13] Negative pressures, however, other than those produced by expanding the chest with the spine extended, have been found: but these are generally small and almost negligible, such values as −0·5 to −1·5 cm. of water having been given by Schreiber. These have been attributed by others either to faulty technique (Moritz), or to pathological conditions—e.g., enteroptosis (Keith).

As in the case of the pressure within the rectum, changing the posture changes the pressure within the stomach. As the average of numerous observations on himself, Moritz gives the following:—

Lying on back	6·3 cm. H_2O	equals	4·6	mm. Hg.
Sitting	8 ,,	,,	5·8	,,
Standing erect	7 ,,	,,	5·1	,,

Thus the pressure in the stomach when sitting is slightly greater than when standing, and when standing is greater than when lying down; in all positions it is considerably above the atmospheric pressure, but what is of greater significance from the point of view of causation of this pressure, it is slightly greater in the upright posture than when lying down. This compares very well with Schatz's observation[23] that while the pressure in the rectum on standing erect measures 28 cm. H_2O, on sitting it is increased to 32 cm. H_2O, but on lying down falls to 14 cm. H_2O. It must be stated, however, that Schwerdt[24] gave higher values for the horizontal (13·5 cm. H_2O) than for the upright (11 cm. H_2O), and I also found a similar condition in a pregnant woman near term. My observations on stomach pressure, however, have been insufficient to form an opinion on this matter. From the work of Moritz[17] and the evidence of accurate and extensive observations his paper contains, however much one may disagree with his interpretations of his results, the figures he gives may be accepted.

Just as the pressure in the rectum is increased when the subject rises from the recumbent to the erect posture, so the pressure in the stomach is increased when the body is lowered from the horizontal position and inverted, by which means the stomach occupies the lowest part of the abdomino-pelvic cavity. Thus Moritz found:[17]

Lying flat on back	7 to 8 cm. H_2O	equals	5 to 5·8	mm. Hg.
Body inverted (i.e., thorax depressed)	20 ,,	,,	14·7	,,
On back again	6·5 ,,	,,	5	,,

A repetition of the experiment gave:—

Body inverted	19 cm. H_2O	equals	13·9	mm. Hg.
Flat on back	7 ,,	,,	5	,,

It is to be noticed that the figures representing the pressure in the stomach when it is dependent are much less than those found in the rectum in the erect posture. If gravity is the effective cause of the pressure, surely the pressure in the stomach, when the body is inverted, should be approximately equal to that in the rectum in the erect posture.

Activity produces considerable elevations of the intragastric pressure, just as it does of intra-rectal pressure; during the change from one posture to another considerable increments of pressure occur. Thus, moving the arms or legs, or holding a weight at arm's length, produces an increase. Schwerdt found the intragastric pressure increased from 11 cm. H_2O to 24 cm., when 5 kg. were held with the arm stretched horizontally forwards, and that it reached 59 cm. when 10 kg. were so held. Keith found on bending down and lifting a heavy weight, the pressure within the stomach rose to over 70 mm. Hg.

CAUSES OF VARIATION OF PRESSURE-VALUES.

From these measurements it is obvious a considerable range of pressure occurs within the abdomino-pelvic cavity. The pressure is different in different parts for the same posture; it changes in the same part with change of posture; and considerable elevations occur with active movement. The question is, What is the cause of these pressure-values, and why do they vary so? To get at this we must analyse and critically examine them.

There are but three factors, by the summation of which the pressure within the hollow viscera, as measured clinically, is produced. First, there is a possible pressure caused by the viscus itself, due to the musculature in its

walls actively contracting on the contents. Next, there is the pressure imparted from the viscera above in virtue of their weight; the remarkable changes occurring with change of posture appear to show its importance. Last, there is the pressure caused by a compression of all the viscera by the body wall and diaphragm enclosing them; as is evident at least from the changes of pressure produced by activity.

POSSIBLE PRESSURE CAUSED BY THE VISCUS ITSELF.

It is first necessary to discover whether the visceral walls participate in the production of the pressure-values, to an extent at least of masking the other factors. At first sight it seems that they do so; that they possess a certain degree of tone, rhythmically varying; and that visceral processes can only occur by their increased contraction. And yet in the case of the cardiac region of the stomach, and in that of the rectum in the intervals between successive defæcations, from which viscera the pressure-values given were obtained, all the evidence points the other way; that the pressure caused by a tonic contraction of their walls is so small as to be negligible from this point of view. There is no doubt that during active visceral processes a rise of intravisceral pressure occurs quite apart from any pressure outside the viscus. Moritz has shown that the passage of food from the stomach into the duodenum is determined by an active contraction of the pyloric part of the stomach, with the production of very considerable pressures within this part, rhythmically recurring; yet he also showed that during the same act variations of pressure within the cardiac part of the stomach, due to a contraction of its wall, did not occur or were so slight as to be scarcely perceptible. Indeed, from the pressure record he obtained, it seemed the stomach was quiescent even after a large meal had been eaten, whilst, in fact, it was digesting and passing the food onwards, as shown by its being empty at the end of the experiment. The only noticeable pressure changes occurring in the cardiac part of the stomach during this process, the observation of which lasted for four hours with a short break, were elevations due to respiration and those caused by the cardiac beat; these were considerable, and, of course, not due to a contraction of its walls. No one will think that defæcation occurs without a considerable rise of rectal pressure due to a contraction of its own musculature, but in the intervals between the acts of defæcation what evidence is there of any marked contraction or even of tone in the rectum? And, naturally, for these clinical observations one chooses a quiescent interval. The fact that all the viscera are closely packed within the abdominal cavity, in consequence taking definite shapes, and the occurrence of a negative pressure within the pelvic viscera when the abdominal walls are relaxed, as in the knee chest position, clearly indicate the tone of the visceral musculature is so trifling that the hollow viscera are readily affected by changes of pressure immediately outside them.

Moreover, if a pressure within the hollow viscera is necessary for their functioning, and if such a pressure already prevails within the body cavity, there seems no reason for the visceral walls to be sustained in continuous contraction of any extent, or indeed to contract at all, unless the pressure within, as in the antrum pylori, is to become for some reason or other considerably greater than in adjoining parts. The function of the hollow viscera is not only to propel their contents onwards, but their walls are actively engaged in glandular, assimilative, and excretory work, just as the pancreas, liver, and kidneys; and whilst at first sight one inclines to the notion that a tonic contraction of the hollow visceral walls occurs and must influence the pressure, because of the existence of their musculature and the known tonic contraction of smooth muscle in the vascular system, we find in the solid viscera, equally important organs, no musculature other than that belonging to their vessels, so that these at least have not the means themselves to produce a pressure within them, except that caused by a swelling of their cells combined with the resistance of their capsules. In line with this, we find the visceral musculature characterised by the extraordinary slowness of its contraction; whilst the body wall muscles are remarkable for the rapidity with which they react as well as for their power of sustained contraction. It is evident that the rapid changes of pressure found in the hollow viscera to result from movement, and the considerable excursions which occur, are due to the rapid sequence of contraction and relaxation of the body wall muscles and diaphragm, not to any supposed alteration of tone or contraction of the visceral walls themselves; for the variations of pressure occur simultaneously with every movement of the patient—the mercury in the manometer responds immediately to such change—and, moreover, they correspond with the magnitude of the movement, being greater when the movement is greater, less when the movement is less.

PART PLAYED BY THE VISCERA IN VIRTUE OF THEIR WEIGHT.

Whilst it will be generally admitted that the elevations of pressure incidental to movement are caused by the increased contractions of the body wall muscles and diaphragm, difficulty arises when we consider the cause of the pressure found during the maintenance of posture; such different values are found in the rectum in the erect and recumbent positions that at first sight it seems the rectal pressure must be due to the weight of the visceral column above it; and the great majority of writers, with the notable exceptions of Schatz, Schwerdt, and Keith, believe the visceral weight to be the determining factor. Moritz was so impressed with the results of change of posture on the pressure values he obtained that he attributed the intra-abdominal pressure to the effects of gravity almost entirely, and thought if the enclosing walls play any part it is but a very restricted one. Thus he explained the differences in the intra-gastric pressure obtaining between the upright and horizontal positions to the different extent the liver weight is transmitted to the stomach in each position, for when standing or sitting the liver must press more on the stomach than in the dorsal decubitus. Yet the differences between the pressures given by Moritz for these several positions are so small as to make one doubt the validity of this explanation. Whilst the intragastric pressure when standing is 7 cm. H_2O, when lying down it is still 6·3 cm. H_2O. One would think, if the liver weight is the main cause of the pressure when standing, that in the dorsal decubitus a considerable fall should occur. More significant is it to find that in the two vertical postures—sitting and standing—in which the liver weight, as Moritz admits, is the same for each, a difference in pressure occurs, actually greater than that between the pressures found when standing and lying down. Moritz explains the difference between these two vertical positions as probably caused by the alteration of the inclination of the pelvis and a diminution of volume of the abdominal cavity, which the change from standing to sitting causes, with a resulting increase of pressure. But how such increase of pressure can occur unless the abdominal wall and other enclosing musculatures participate is difficult to understand. And if the increase of pressure found in sitting over and above that found in standing is due to muscular action, it is just as likely that the lesser increase found in standing over and above that found in the dorsal decubitus is similarly produced; and further, if the enclosing muscles play a part in the pressure variations which occur with change of posture it is as likely as not they are concerned in the maintenance of the pressure during posture.

When we come to examine the pressure values found in the rectum for different postures the same conclusion that the visceral weight is inadequate as the only or the main cause is also forced upon one. One can scarcely attribute the pressure in the left lateral position—6 to 8 mm. Hg—to the weight of superimposed viscera, for the rectum lies buried in the rigid pelvis and the part in which the pressure is measured—the rectal ampulla—abuts against the concavity of the pelvic floor, and the rigid side of the pelvic cavity arches over it as a sort of roof, and in this position there are no superimposed viscera. Equally convincing is the significant increase of pressure which occurs when the patient turns from the left lateral position on to the back, lying flat and at ease. The increase may be so great that the pressure is doubled, and, more remarkable still, on standing the pressure may be only further increased by a similar amount. These results compare very favourably with Moritz's observations on the stomach pressure for corresponding positions. In the right lateral (i.e., in which the liver weight is put out of court and the patient lies on a couch) the intragastric pressure was 3 to 5 cm. H_2O (2·2 to 3·7 mm. Hg); but on turning on to the back it rose to 6·5 to 9 cm. H_2O (4·7 to 6·6 mm. Hg); whilst on standing erect the pressure averaged 7 cm. H_2O (5·1 mm. Hg). Since the weight in the dorsal decubitus is borne by the extensive surface of the posterior abdominal

wall and is thus distributed over a wide area, one cannot concede that gravity can be the cause of such an increase of pressure in the rectum which occurs on changing the position from the side to the back. Nor can one attribute the pressure in the rectum when standing erect to the effect of the visceral weight, since the increase which occurs with change from the dorsal decubitus to the erect posture is no more, or not much more, than occurs on turning from the side on to the back.

Moreover, the effect of inverting the body on the pressure values found in the, for the time being, lowermost and uppermost poles of the visceral mass is altogether discordant with the hypothesis that the pressure is due to the visceral weight. For when standing the pressure in the rectum is 20 to 28 mm. Hg, whilst in the inverted, or at least in the knee-chest, position it sinks to − 6 to − 8 mm. Hg, but for corresponding positions the pressures in the stomach are 5 to 6 mm. Hg and 14·7 mm. Hg respectively. The effect of inverting the body is, therefore, to cause a much greater difference of pressure in the rectum than in the stomach, in spite of the visceral column being approximately the same. It is clear the weight of the superimposed viscera is insufficient to explain the pressure values found, and if the pressure in the stomach in the inverted position is due to the weight of the superimposed viscera, as is probable, the pressure in the rectum in the erect posture must be due to some other additional force. The only explanation can be that in the two postures the tension of the enclosing muscles is different; that in the erect position it is high, in the inverted it is low.

But the increase in tension in the erect posture is not everywhere the same, for if even the abdominal wall had merely to overcome the influence of gravity on the viscera, the lower, infra-umbilical part would have to offer a greater resistance than the supra-umbilical part, just as the lateral pressure of a viscous fluid on the side wall of a vessel containing it increases with its depth. But in the erect posture the increased tone of the infra-umbilical belly wall as compared with that of the supra-umbilical is required, not because, or merely because, it has to bear a greater part of the visceral weight—it has, indeed, to overcome the tendency of the viscera to sag downwards and to resist as well the effect of the contraction of the enclosing wall above—but because it has to force the blood in this part of the body cavity, and that coming from the lower extremities, to a greater height—viz., to the thorax. This necessity is clearly evident in the erect posture, but when the body is inverted it disappears.

COMPRESSING EFFECT OF THE ENCLOSING MUSCULATURES.

These considerations dispose of gravity as the effective cause in the production of the intra-abdomino-pelvic pressure for most postures—a conclusion confirmed by finding a positive pressure in the stomach in the erect posture at ease. Were gravity the only factor concerned, the pressure in the stomach should be at least not positive; indeed, we should expect it to become negative, just as the pressure within the rectum actually becomes in the knee chest position. The only alternative is that the effective factor in the pressure formation for most postures, just as it is the one to which the great excursions of activity alone are due, is the compressing effect of the musculatures enclosing the viscera; that the intra-rectal and intra-gastric pressures are due for the most part to the general pressure within the pelvic and epigastric poles of the visceral mass respectively, and are caused by the viscera pressing against each other and against the walls enclosing them; and that the differences in pressure found in these parts in any one posture except unnatural positions, such as the knee chest or inverted, are due more to a *difference in tension* of the respective segments of the musculatures than to the effect of the weight of the superimposed viscera, which, though playing some part, appears to be more important than it really is, at least in the erect posture, the position of activity.

INTRA-ABDOMINO-PELVIC PRESSURE AND THE CIRCULATION.

Coming now to the physiological significance of the intra-abdomino-pelvic pressure, indications have already appeared that its function is a circulatory one, and that by this means it affects the body as a whole.

As we have seen, the abdominal wall and thoracic diaphragm are antagonists, opposing each other, and doing so by means of the viscera in virtue of their bulk and incompressibility. In other words, they are coördinated; and in this coördination the pelvic floor musculature participates, and it would be strange if the thoracic musculature were not similarly involved. The purpose of all these musculatures is to cause a pressure effect within the body cavity, to the end that a greater pressure shall prevail in the abdomen than in the thorax, just as in the abdomen itself we find evidence that the pressure in the lower part is greater than in the epigastrium even in the supine position (rectal press. 10 to 14 mm. Hg and stomach press. 4 to 5 mm. Hg).

At first sight it seems the function of the diaphragm is a respiratory one, causing an entry of air to the lungs and this alone; but Mosso[18] and others have shown that more air can be respired by a purely thoracic breath than by a purely abdominal one, and thus costal respiration is the more effective from this point of view, as it was the primitive method of breathing. But respiration, to serve its purpose, requires not only that the stale air in the lungs should be refreshed by an additional supply, but that the lung tissues should be simultaneously flooded with an increased volume of blood. This accession of blood during inspiration is determined to a certain extent by the fall of pressure in the thorax itself, which acts, as Lewis[16] has shown, by diminishing the pressure in the pericardium. Thus more blood passes through the lungs on inspiration; and this results, perhaps, as well by thoracic as by diaphragmatic breathing, since both increase the negative pressure in the pericardium; although the influence of the diaphragm may be greater in this respect because of its direct attachment to the pericardium. This is supported by the phylogeny of the diaphragm, for, as Keith has shown,[14] it was primarily a circulatory muscle, directly influencing the dilatation of the heart by a traction on the pericardium.

But the diaphragm, by increasing the pressure in the abdomen, has a further effect than this. Leonard Hill[7] has demonstrated that if the inferior vena cava be opened in the thorax in a cat each time the diaphragm descends blood gushes out, and in the intact animal it gushes from the abdomen into the large venous reservoirs directly connected with the right heart, which is thus supplied with a larger volume of blood, and consequently the general blood pressure rises. But when respiration is purely costal the usual inspiratory rise of intra-abdominal pressure may fail, or even fall below zero, the compression of the abdominal viscera lessens or ceases, no such gush of blood occurs, and the general blood pressure falls (Lewis). This, then, is a reason for believing that the average arterial (aortic) blood pressure is lower in the thoracic type of breathing, as in reptiles and birds, than in the abdominal or combined type, as in mammals; and that in woman, who certainly uses her diaphragm less than does man, the general blood pressure is lower than in the male (Oliver[19]),‡ and may explain the fact that in man himself breathing generally becomes thoracic in the supine position (Mosso), in which posture an aortic blood pressure for the supply of the brain may with safety be lessened.§ Thus, the intra-abdominal pressure influences the aortic blood pressure, raising it, and other things being equal, increasing the blood velocity towards distant parts. By this means not only are the viscera themselves and the skeletal muscles better supplied with blood, but more especially the brain, carried high on man's shoulders, is adequately and rapidly provided for, in spite of the opposing action of gravity. Thus, in enteroptosis, in which the intra-abdominal pressure is lower than normal, we find all the symptoms of neurasthenia appear.

INFLUENCE OF INTERNAL PRESSURE ON THE VISCERA.

But there is another result of the intra-abdomino-pelvic pressure, and that is its influence on the viscera themselves. Quite apart from the maintenance of the several organs in their respective positions within the body cavity, which the compression of the whole visceral mass by the ever-contracting muscles enclosing them cannot help but determine, and which is their most obvious and perhaps least important function, the pressure so caused has other purposes. Clearly it tends to limit the distension of organs, and probably is an effective agent in preventing undue dilatation of the hollow viscera, as for example, may occur from fermentative processes. This it may do in two ways, either directly by

‡ In women the pressures are generally from 5 to 10 per cent. less than in man.

§ See also François Franck.[4]

supporting the viscera, or indirectly by influencing the circulation through them, and this probably is much the more important. For by compressing these viscera within certain limits it supports the capillaries within them, and thus by raising the capillary blood pressure it increases thy velocity of blood flow through them. Thus it materiall affects the metabolism of the hollow organs and other abdominal viscera, assisting and hastening it.

As is well known, disorders of digestion are perhaps the most frequent concomitants of early enteroptosis; and nothing cures these cases of flatulent dyspepsia more efficiently than a routine involving muscular exercise, such as golf; the resulting increased tone of the whole muscular system affecting the body-wall muscles as well as those of the limbs, and the capillary circulation of the stomach and other viscera becomes improved. That the intra-abdomino-pelvic pressure has such an effect on the visceral circulation becomes clear when the dynamics of the capillary circulation are considered, of which Dr. Leonard Hill is such an able exponent.

It may, of course, be objected that the thin-walled capillaries, permeating the viscera, could be easily obliterated, especially when the intra-abdominal pressure is very greatly raised, as during straining and violent movements; and, becoming greater than the blood pressure in the arterioles supplying them, the capillary circulation would, for the time being, cease. And no doubt this occurs, at least to some extent, just as when a muscle hardens, the capillaries within it must be occluded. But such elevations are usually brief, so that the cells do not suffer. It is probable that elevations of internal pressure are associated with, or cause reflexly, a dilatation of the visceral arterioles, just as the arterioles of a muscle dilate when the muscle hardens; and so when the phase of relaxation succeeds the phase of increased tension or contraction, a considerable flooding of the visceral area, as of the muscle, occurs. At least it is well known that violent exercise, such as horse-riding, influences most beneficially what people call "their liver," and this can only occur by means of the flow of blood through the visceral capillaries being affected.

Thus, the intra-abdomino-pelvic pressure, even that maintained during posture and rest, subserves most important circulatory functions. It not only quickens the whole circulation, but renders the blood richer and purer in a shorter time; and this is the reason of its far-reaching effects on general metabolism. By maintaining a high aortic pressure it lays the foundation for an efficient cerebral circulation so important to man; it is, indeed, by its means that man has been able to evolve and is able to maintain a vigorous and strenuous life, both physical and mental, in spite of his erect carriage and the elevated position of his brain.

In conclusion, I would again emphasise the importance of this pressure. Unfortunately, the subject is not only of academic interest, for aberrations from the normal abound amidst the populace, and in my experience form perhaps the commonest of the ills to which man is heir.

A YEAR'S WORK IN

ABDOMINAL AND PELVIC SURGERY

IN THE ROYAL VICTORIA INFIRMARY, NEWCASTLE UPON-TYNE, AND IN A PRIVATE HOSPITAL DURING 1910.

BY RUTHERFORD MORISON, M.A., M.B., F.R.C.S. EDIN. & ENG.,

PROFESSOR OF SURGERY, DURHAM UNIVERSITY; SENIOR SURGEON, ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE.

STATISTICS of an exceptional character have a value of their own. They show what *can* be accomplished by skilful operators who make a careful selection of cases, or who have had exceptionally fortunate experiences; but they are apt to mislead practitioners unacquainted with the details and the difficulties of surgical practice, and also to induce too confiding patients into the belief that surgical operations can be undertaken with impunity.

A record of every operation performed during a whole year seems to me to represent the best method of indicating the probabilities of success or failure, as against indication of those possibilities which are of little use to the majority. The statistics offered (Tables I. and II.) refer only to operations performed by myself, and apply not only to the viscera but to all the structures of the abdomen and pelvis. The relative paucity of minor and of emergency cases is due to the fact that the great majority of these are operated upon by the junior staff.

In a former paper of mine[1] the statistics of my abdominal and pelvic work during the period of office of my last full-time house surgeon in the old infirmary (November, 1905, to February, 1906) were given, and it was suggested that they might later prove of some historical interest. Until the latter end of 1909 it was difficult in the new infirmary to get any satisfactory statistics, and impossible to obtain proper records of cases, as there was only one surgical registrar for the whole institution. Since then each surgeon has had a registrar of his own, and a complete record of the surgical work has become possible.

In the paper referred to it was stated that the old Royal Infirmary of Newcastle—which was vacated in 1906—established claim to be considered the worst hospital in the British Isles, as certainly as the present institution can claim to be the best. It is of interest to compare our surgical results in the miserable and apparently inadequate place we left with those obtained in the costly and palatial building in which we now work.

In the paper quoted above I wrote:—

> So far as I can judge, the only serious drawback in connexion with the old building was the frequent occurrence of pneumonia after, or even independent of, operation.

Even this, however, is now discountable, in view of the fact that pneumonia appears to be as prevalent in the new as it was in the old institution, the structural defects of which must be exonerated from special blame.

It seems to me certain, since our experience has proved it, that surgical results are not influenced by the costly and elaborate arrangements of the modern hospital, but that they depend upon strenuous personal endeavour on the part of everyone concerned to carry out the simple essential requirements of present-day surgery.

I am responsible for the charge of 48 beds, and the staff comprises an honorary surgeon, an honorary assistant surgeon, an honorary registrar, an honorary house surgeon, a paid anæsthetist (he receives £80 a year), and an indefinite number of dressers, varying from two to six, according to supply. There are three sisters in charge of the wards in which I am interested, but only one of these (in the male ward) works solely under my supervision, for in the women's and children's wards more than one surgeon acts. Each of these wards has, in addition to the sister, one staff nurse and three or four probationers.

The operating theatres, four in number, are supervised by

* Five partial gastrectomies (4 recoveries and 1 death) have been also included under posterior gastro-enterostomy; 1 perforating duodenal ulcer has also been included under the same heading; and 1 perforating pyloric ulcer (recovery) under pyloroplasty. In making out the totals, these have only been counted once. In the extended list, therefore, 7 cases are down twice.

a sister, who is in charge of them all. The theatre in which my work is done has an instrument nurse, a sponge nurse, and an assistant nurse to do whatever she may be told.

Only the senior staff has any permanency. From the house surgeon onwards there are constant changes, each house surgeon being appointed for only six months of office. The fact that the chief object of the institution, apart from its duty to patients, is educational is fully realised, and though it is disappointing for the surgeon to know that almost as soon as assistants and nurses have gained the necessary skill to be of value to him it is their turn to leave, the experience is not altogether of disadvantage, if he constantly remembers that the best way to keep himself up to the mark is by teaching others.

During the early days of a complete change, however, the position is often a more trying one for the surgeon than any would suppose who have not experienced it. Each member of the senior staff is so fully occupied with his own work that he can attend to little else, and the most difficult undertaking must be faced with unskilled and frequently with too few assistants. This is wrong, and with regard to this matter, as in some others, a revolution is surely impending in the conduct of our hospitals.

Selection of Cases for Operation.

There is no more difficult problem in surgery than that which presents itself in making a proper selection of cases for operation. Anatomical, physiological, and pathological knowledge, diagnostic acumen, prognostic capacity, are all requisites of the good surgeon. Anyone can become a surgical mechanic. Capable surgeons are not so easily produced. It is so easy and so safe to cut everywhere "to see" that the surgeon is encouraged to operate in any case and in every case. The public applauds because something has been done. The surgeon and the public are apt to forget, until they receive an unpleasant reminder, that it may sometimes be wise to do nothing.

The first principle to bear in mind is that there is no special surgery of the abdomen, pelvis, or other region, as the text-books lead us to believe. The general principles of surgery must be observed in respect to all parts of the body, though neglect of this or that canon may be followed by more serious consequences in one part than in another.

One of the most important indications for operation in the abdomen, as elsewhere, is in connexion with *arrest of hæmorrhage*. Spontaneous hæmorrhage from any of the abdominal viscera, like spontaneous hæmorrhage from other parts of the body, is not subject to general laws, and each individual case requires consideration, if harm is not to result from operations undertaken to arrest it.

On the other hand, intraperitoneal hæmorrhage is a definite indication for an operation undertaken in order to see the bleeding point. If this principle had been kept in mind, the "lesson of the South African War"—to leave punctured

wounds of the abdomen alone—would have included an emphatic exception in cases presenting symptoms and signs of intraperitoneal hæmorrhage, and the useless discussions and dangerous divergence of opinion as to "when to operate" in cases of leaking or ruptured ectopic gestation would have been avoided.

The next indication for operation I have to offer is in connexion with *wound exploration*. It should, for example, be a rule that no wound of the abdominal wall should be left without full exploratory operation. The object of this is to see, or at least to feel, the whole track of the wound. If the peritoneum is intact it should, of course, not be opened, but if perforated the fact should be known and action taken accordingly. Foreign bodies and dirt should be discovered and removed always and everywhere—an important point.

There are some *abdominal injuries other than external wounds* which indicate early operation. A sudden severe and sharply localised blow—such as that received when a horse kicks the abdomen—is practically certain to cause a rupture of some abdominal viscus, usually the small intestine. It is time to teach that such a history affords, by itself, a definite indication for operation. All doubts in doubtful cases should disappear if there are increasing pallor, increasing thirst and restlessness, with increasing rapidity of pulse, suggesting hæmorrhage; or if there are continued severe pain, marked local tenderness, muscular rigidity, thirst, vomiting, and a quickening pulse, indicating a leak in the gastro-intestinal tract. Operations performed early in these cases are remarkably successful; performed late they had often better not be done.

Prevention of Sepsis.

Sepsis is still the great cause of surgical mortality. Seldom at the present day due to defects in technique or wound

treatment, it is from failure to remove early enough the source of sepsis that disasters result.

There would be no percentage of deaths from *appendicitis* if every case commencing with acute pain [2] and developing tenderness and rigidity of the abdomen, and quickening of the pulse was operated upon within 12 hours. Surgeons can scarcely be blamed for the present deplorable death-rate. In season and out of season I have spoken out for more than fifteen years, and in every paper which I have written bearing on the subject I have emphasised the importance of removing the inflamed appendix in time to prevent septic infection of the peritoneum, recovery from which can only follow a dangerous and prolonged illness, with the possibility of a ventral hernia at the end of it. There is no other definite indication for operation in appendicitis, and none other needed, if only the vista of risks ahead is duly appreciated.

The prevention of sepsis should also be the aim of the surgeon in operations for *perforating gastric and duodenal ulcers*. Statistics I have recently published [3] corroborate all recent information to the effect that if these ulcers can be closed during the first 12 hours—i.e., before sepsis has secured too firm a hold—the patient's recovery can be confidently anticipated. If, on the other hand, delay has allowed of the development of general septic peritonitis, the chances of recovery are small, and may be rendered even smaller by operation. The totality of reasons for or against operation in these cases requires careful consideration.

The dangers of serious and destructive sepsis depending on the presence of gall-stones, bladder-stones, and kidney-stones, constitute the strongest of reasons for their early removal.

To Deal with Mechanical Obstruction.

No more important or more definite indication for operation can be offered than this. When a calculus is causing obstruction the symptoms are so grave, and the results likely to be so destructive, that the diagnosis should carry with it the recommendation of operation.

In regard to *kidney and ureter stones*, X rays show not only the presence of a stone or stones, but also their size and position. Only the smallest which have arrived at the lower end of the ureter should be left to the chance of passing by nature's effort. Elsewhere their operative removal, by skilled hands, is attended with less danger to life and to the integrity of the organs concerned than is their escape by the processes of nature.

The same holds good of *gall-stones*. Their removal by operation from the gall-bladder is safe and easy, and the results are satisfactory. After they have escaped into the ducts, however, the operation for their removal is likely to be dangerous and difficult. The most skilled operator may fail to find some of them, and recurrence of the attacks, or imperfect recovery, the result of septic changes in the ducts, liver, and pancreas, are not uncommon.

Short-circuiting off an obstruction in the gastro-intestinal tract has of late years become a useful and "fashionable" operation. For example, there is no indication so suggestive of the need for gastro-enterostomy as that provided by an ulcerating stricture at or near the pylorus. Entero-anastomosis has also very properly taken the place of enterostomy and colostomy in many cases of irremoveable stricture of the intestine. Instead of removing hydronephrotic kidneys, plastic short-circuiting operations are frequently done on the pelvis and ureter. Jaundice due to irremoveable mechanical obstruction can be cured by cholecystenterostomy.

The need for operation in cases of *intestinal obstruction* is universally conceded, since few cases are due to other causes than removeable mechanical obstacles; *but* the need for early operation has not yet received the recognition it should have received, and this is because the necessary diagnostic rules for intestinal obstruction are hard to formulate, and because without definite diagnosis a sufficiently early operation is seldom strongly enough urged.

The dangers of strangulated hernia and acute intussusception no longer exist, since early diagnosis and prompt operation have evaded them. The dangers of acute intestinal obstruction arising from other causes are still deplorable because the difficulties of early diagnosis have led to delay, and delay in the proper treatment of these cases means death.

Twists (volvulus) of the viscera cause such urgent and definite symptoms at their commencement that it is often possible to make an early diagnosis. I think it is not too optimistic to hope that a time will come when operation may be done on these cases soon enough to prevent the avoidable loss by gangrene of intestine, testicle, or ovary.

To Remove a Focus of Disease.

This is the most important of all indications for operation. Much that has been stated above would come under this head. It is *the* indication for operation in septic cases. In tubercle and cancer it is of prime importance, for it is almost certain that both of these commence locally, and for a time remain localised. Excision undertaken early enough would prevent all further development. An operation too deferred, when either disease has spread beyond the limit of the primary focus, would offer a very different prospect of success.

Exploratory Operation.

No other surgical measure requires such care and judgment as this, if good rather than harm is to follow. It is not enough that there exists a doubt in diagnosis which can only be cleared up by such an operation. There should be a reasonable probability of something organically wrong, something which demands treatment, and something likely to prove amenable to the mechanical methods of surgery. The less these conditions are satisfied in any particular case the more clear it is that operation is unnecessary, that more harm than good is likely to be done, and that the patient is exposed to risks which cannot be foreseen. One success should not be regarded as fairly balancing many failures, and it should further be realised that the discovery of unsuspected disease is seldom to the advantage of the patient or to the credit of the surgeon.

Speaking personally, I have no hesitation in saying that nothing in my practice has brought me such unhappiness as has exploratory operation. After a roving commission in the abdomen, and the removal of gall-stones, of a diseased appendix, and of an ovarian cyst, all necessitating the separation of many adhesions, I have found patients who were not only no better, but louder than ever in their complaints after their pathology had been fully dealt with. This has occurred to me often enough to prove that it is no coincidence.

Above all else in surgery stands the need for definite pathological knowledge, for an exact diagnosis of the lesion to be dealt with, and for courage enough to do nothing when the abdomen is opened unless there is a clear indication afforded on general surgical principles.

If an operation has been undertaken it is necessary that it should be completed. There should be no limit to either its duration or extent, if the completion of it offers, from a scientific point of view, a chance of life. Incomplete operations are never satisfactory and are more disastrous in their results than the most heroic when thoughtfully planned and skilfully executed.[4]

Contra-indications to Operation.

Operations, unless absolutely necessary for good surgical reasons, should never be undertaken on patients in whom nervous symptoms predominate. There are many unfortunate individuals with gastric, or intestinal, or hepatic, or renal, or testicular, or uterine pains known to every surgeon, and only too willing to undergo operation. Some of them the operation will cure; the majority, though relieved by it, acquire some other ailment equally troublesome, and a powerful minority, "made worse," preach in season and out of it against surgeons and all their works.

Another class suffers from indefinite abdominal ailments and seriously defective health. Some have proptosed viscera, ptosis of the stomach or colon, movable liver or kidneys, mucous colitis, chronic appendicitis, prolapsed ovaries, intestinal adhesions, &c. Many ingenious operations have been devised for their cure, but fixations, appendicostomies, plications, appendicectomy, the separation of adhesions, have all proved dismal failures. The future will show how far Mr. Arbuthnot Lane's brilliant work on resection of the colon will fulfil its present promise. Allowing for this exception, it is safe to say that, like the class previously referred to, they are cured, or relieved, or made worse by one or many operations.

[2] The history of the initial pain may be the most important evidence of an acute abdominal emergency when the patient is seen later.

[3] British Medical Association Annual Meeting, 1911.

[4] See paper of mine, "Mistakes in the Technique of Abdominal Surgery," Edinburgh Medical Journal, July, 1893.

Meanwhile these cases are not at all for the surgeon. Faith healing, "Christian Science," and Lourdes have already a far greater percentage of cures than surgeons can show. Further competition in a race so uneven is bad for the credit of surgery.

There are certain palliative operations which are useful, but which should not be done except as a last resource. They are such as entail discomfort through departure from the plan of the normal exterior of the body—e.g., gastrostomy for malignant stricture of the œsophagus, and colostomy for inoperable stricture of the large intestine. When a patient is hungry, and recognises that without surgical aid he is going to die by starvation, then an operation will prolong his life, and he will be grateful for the result of a gastrostomy. Many patients with malignant stricture of the œsophagus can swallow enough to keep them going, never feel hungry, and have no great desire to live. Gastrostomy will prove no blessing to them.

No operation gives more relief or satisfaction to a patient with intestinal obstruction than inguinal colostomy, but this is an operation which has been much abused. Because it is easy and safe it has been exploited in the treatment of a variety of conditions, in which I have heard patients many times declare that "the cure was worse than the disease." Careful attention and a considerable time devoted to unsavoury details will do much to make these patients' condition tolerable; but to suggest, as is sometimes done, that the operation is a surgical triumph shows an optimistic disregard for what ordinary intelligent people think about it.

Preparations for Operation.

Except in cases of emergency, our rule is to admit patients to hospital two days before operation. Careful examination is made of the general condition, of the mouth and teeth, of the lungs and heart, and of the urine. On the morning before operation one ounce of castor-oil is administered, and previous to operation a soap-and-water enema. Immediately before the anæsthetic is administered the mouth is rinsed out and the nose cleansed.

The skin covering the abdomen is prepared the night before the operation, first by thorough mechanical cleansing with spirit soap and hot water, and then by the application of a towel wrung out of alcohol, which is worn till the operation. Latterly this has been removed on the operating table and the abdominal skin painted with a 4 per cent. alcohol or chloroform solution of iodine.

All over the world operative technique is now very much the same, and every surgeon aims at keeping his wounds germ-free. That this has not yet been accomplished to the satisfaction of the bacteriologists is universally acknowledged, but surgeons know also that the essentials for safe and successful surgery are simple, inexpensive, and able to be carried out everywhere, if Lister's teaching be followed. Until surgical operations can be conducted with the same certainty as are bacteriological experiments there is room for improvement, and the best surgeons will always be found anxious to adopt suggestions that appear to add something to the chances of asepsis.

Until recent years I used nothing but antiseptics for the preparation of instruments, dressings, and hands. At the present time, in addition to this, I wear an antiseptic overall, boots, gloves, sleeves, cap, and a mask. Everyone engaged in the operation—assistants and nurses alike—does the same. Visitors to the theatre wear sleeveless overalls and masks, while the floor at the entrance to the operating theatre is sprinkled with 1 in 1000 corrosive solution to fix any dust on their boots.

The sterilised *instruments* are covered with 1 in 20 carbolic lotion, and immediately before the operation begins this is diluted down to 1 in 60. The operation site is surrounded with sterilised towels, and on the top of these other towels, wrung out of 1 in 20 carbolic lotion, are placed so that instruments can be laid upon them.

The gloved hands are frequently rinsed in 1 in 10,000 corrosive solution during operation, and any possible contamination implies prolonged and careful cleansing in 1 in 1000 corrosive lotion before the final rinsing in 1 in 10,000.

Ligatures and sutures are all prepared by the theatre sisters. With few exceptions catgut and silkworm-gut only are required. We use thin silk for the outer suture in gastric and intestinal cases, thick silk for the stay sutures in fat abdomens or cancer cases, and silk occasionally to tie a pedicle. The catgut is chromicised by McEwen's method, then boiled in alcohol under pressure, and finally placed in iodine spirit for eight days before use. Prepared in this way, we have had no trouble with it during a period of four years. Silk and the *fishing gut* are sterilised and kept in alcohol.

Mops are made of three types—large square, small square, and long strips. Every mop has attached to it one foot of tape, and a white pot ball the size of a walnut. Two nurses count the mops before operation, and the number is written up on a window, to be seen by everyone. On no account must a mop be cut during operation, and the same two nurses make a second count when closure of the wound commences. To some this may appear more than care. These critics have not seen so many sponges, instruments, and mops left in the abdomen as I have, and consequently do not know so well how easy it is for even the most capable to make such mistakes.

Anæsthetics.—Subject to my approval the choice of an anæsthetic is left to a skilled anæsthetist. When I am entirely responsible I prefer chloroform till the laryngeal reflex is abolished, followed by ether in an Ormsby inhaler

The instrument nurse.

for the rest of the operation unless the respiratory movements of the abdominal wall become too vigorous, or rigidity prevents satisfactory manipulation, when a short return to chloroform is indicated.

Shock.—Though death from "shock" generally means death from hæmorrhage or sepsis, or from both, no one now doubts the separate and independent reality of shock. Little can be done when it has developed: much, on the other hand, to prevent its occurrence. The maintenance of body heat, avoidance of rough manipulations, morphine before operation, and care in regard to blood loss are the chief ordinary measures relied on. In feeble patients, or for prolonged operation, the slow intravenous transfusion of from one to two pints of saline solution (one drachm of table salt to one pint of water), at a temperature of 102° F., or continuous subcutaneous infusion of the same by the method of Mr. Arbuthnot Lane, are invaluable aids in warding off shock.

Incision.—The abdomen can be opened by an incision of any shape or position, but there are two incisions which inflict a minimum of damage on the abdominal walls, and which can also be most readily extended in case of need. These are the ideal incisions. The first is *straight* in the middle line. The second lateral and *oblique*, and runs parallel to the nerves in the abdominal wall.

I have always advocated incisions large enough to allow of sufficiently free access for easy manipulation, and in difficult cases to permit of inspection. These are secrets of good surgery no less in the abdomen than elsewhere, though sometimes forgotten. The longest incision will cause no subsequent weakness of the body wall if it is properly closed and healing is as satisfactory as it ought to be, while the shortest incision *can* allow of a hernia of the scar.

It is impossible to properly deal with such wounds as I have referred to by means of a single layer of sutures. The peritoneum should first be closed with a continuous suture of catgut. This is a most important step, because if any hole is left a portion of omentum—which should always be drawn down over the intestine—will find its way through and then enlarge and stretch the opening for further protrusion.

After the peritoneal suture a series of interrupted or stay sutures of silkworm gut, or silk, are passed through all the layers except the peritoneum, and their ends clipped on either side of the wound. They are inserted one inch apart, and through the skin one inch from its incised margin. The median line aponeurotic tendon or lateral muscles are brought into apposition by a thick strong cat-gut continuous blanket stitch, and the stay sutures are tied. Superficial silkworm gut sutures are used to secure perfect apposition of the skin edges.

Dressings.—Next the wound I use sterile gauze wrung out of alcohol, and over this a voluminous dressing of corrosive wood-wool, with the double object of maintaining heat and allowing of elastic compression by the many-tailed bandage.

After-treatment.

Nothing more clearly shows the advance of abdominal surgery than the changes which have occurred in respect to after-treatment.

All our hospital cases are now nursed in the general wards, and most of them get scarcely more attention than the fracture cases receive, for they do not need it. (Miss Walmsley, matron, reports that during 1910 only four patients were nursed by special nurses in my ward.) So long as these patients are sickly no food is allowed them—only water to drink. On the third or fourth day one ounce of castor oil is administered, and after this ordinary diet is gradually resumed. The dressing is changed, and the superficial skin sutures are taken out, on the tenth day. I often shiver when reading accounts of cases to learn that *all* the sutures were taken out on the tenth day. A fit of coughing, an attack of vomiting, a sudden gripe, may burst a wound open and allow intestine to extrude. This would almost certainly happen in cancer cases where the healing capacity is always deficient. Three weeks, as a rule, should elapse before the removal of the deep or stay sutures.

Thirst is always a troublesome symptom after operation. There is no good reason why patients should not be allowed to relieve it by drinking when they want to. If the water is cold, and it is for this they crave, too much should not be taken at a gulp. To be allowed a feeding cup constantly replenished with cold water, and to be sipping at it most of the time, gives them greater pleasure than anything else.

Sickness.—Any serious sickness can only be satisfactorily dealt with by washing out the stomach. A frequent result is that the continuous nausea and urgent vomiting which have resisted all the usual remedial measures tried, both cease after the first washing.

Morphia.—The pain following an abdominal section is usually greater than that associated with any of the ordinary or extraordinary illnesses of life, and my opinion is that it should be relieved. A long experience has convinced me that the advantages obtainable by the use of morphia exceed the disadvantages. Our rule is to give a quarter grain hypodermically the first night.

Bowels.—A trinity of symptoms follows every operation in which the peritoneum is opened: all patients are more or less sick, griped, and thirsty.

The gripes are relieved by the passage of flatus, and depend, I think, on irregular contractions of the muscular intestinal coat. Wearing a rectal tube may be an aid in mild cases, and a hot dry bran-bag over the dressing may give some relief. By the end of the second day, if flatus has not been passed, one ounce of turpentine suspended in a tumblerful of barley water, and followed by a pint of soap and water, may be administered as an enema. This can be repeated every two hours if necessary. On the fourth day one ounce of castor oil is given to all of my patients. Nothing else, so far as I have yet discovered, has the wonderful effect of this nauseous dose.

It is a good rule, at least in serious cases, not to give any food by the mouth so long as there is sickness, or until flatus has been passed.

In any case which is serious, either as the result of disease or of the operation, the continuous administration of normal saline by the rectum is an invaluable aid. The good effect of this is especially noticeable in cases of septic peritonitis, when the hollow-eyed, grey, Hippocratic face and the running pulse can be replaced in a few hours by a condition that indicates no grave illness.

Bladder.—The fashion of passing catheters in abdominal cases has largely disappeared, and with great advantage to the patient. A new house surgeon, however, requires to learn that a patient with no marked urinary symptoms may have a dry tongue and not be doing well because the bladder is not properly emptied. Especially with old people and women examination of the hypogastrium may offer a surprise in the shape of a distended bladder when only "the stomach" is complained of.

Prognosis.—In the majority of cases a prognosis can be offered before the patient leaves the operating table, since hæmorrhage, sepsis, and shock, the three great causes of death, are now to be regarded as complications of the operation, and seldom as the consequences of it.

The nurse.—In the after-treatment of abdominal cases nothing counts for so much as a good nurse. In a previous paper[5] my appreciation of this fact has been expressed:—

> Certain nurses have a knack of doing well with abdominal cases, and both patient and surgeon are lucky if they get hold of such a one. To be raised up comfortably and packed up skilfully with pillows at the back and under the knees into a half-sitting position for a time, even on the second day, is a great relief to most patients. Rolling over occasionally from the back to one side, then to the other, and back again, if it can be done without great trouble, as it can by a skilful nurse, is a change that most patients are grateful for. A little drink, a little well-timed sympathy and encouragement, even perhaps a gentle reproof on occasion, are things certain to make the difference between a happy and an unhappy patient, and I for my part believe that in the majority of serious cases the skilled attentions of an intelligent sympathetic nurse can, and do, account for the continuance of life and for escape from death.

If a patient has made entirely satisfactory progress up to the fourth day it is seldom that anything goes wrong.

Complications following Abdominal Operations.

Peritonitis.—A septic focus already present, which has resisted attempts to deal with it, may be the centre of a spreading infection and the cause of general peritonitis. It is possible, though now very rare, to have post-operative septic peritonitis from mistakes in technique.

The septic infection may be the result of leakage from a viscus damaged sufficiently to allow of its walls giving way later, *but* the most frequent cause, and one which should always be carefully borne in mind, is leakage from an unrecognised perforation. In separating adhesions of the stomach and intestines, or round the vermiform appendix, or in the pelvis, it is easy to make unwittingly a small opening in one of the hollow viscera, and to overlook it, unless the most careful testing is employed.

Whatever the cause of the peritonitis may be, it is usual to note nothing extraordinary till the end of the second or the beginning of the third day. The patient is usually depressed and sickly, the pulse steadily increases in rapidity, some distension of the abdomen, first noticed in the epigastrium, appears and the passage of flatus is interfered with.

The course now to be taken depends upon the diagnosis as to the cause, because another operation may give a patient the only chance left for life, or it may take away the only possibility of recovery. If the illness is the result of an overlooked and unrepaired leak a prompt operation may be life-saving. If the focus of infection cannot be removed or excluded—as in ordinary post-operative septic infection—prompt operation is likely to kill the patient.

[5] Abdominal and Pelvic Surgery, Edinburgh Medical Journal, January, 1904.

The best course in this serious condition, and one not without some hope, is to stop all food and drink by the mouth and the administration of all purgatives, to wash the stomach out frequently so long as there is sickness, to maintain the body heat by artificial means, including large hot applications to the abdomen, to administer as much fluid by the rectum as the colon will absorb, to maintain the heart's action by 1/20th grain injections of strychnine hypodermically every six or eight hours,[6] to give small doses of morphia hypodermically when there is marked restlessness, and if the patient recovers to keep a careful daily outlook for localised collections of pus in the abdomen. These should, of course, be evacuated as soon as discovered.

Pneumonia.—In the paper previously alluded to[7] the following words occur:—

> My impression is that pneumonia following operation in Newcastle Infirmary is much more common than elsewhere (it occurs in about 10 per cent. of my cases), but so far as I can judge it is the only serious illness *dependent on our overcrowded and insanitary building.* (Italics not in original.)

It is still true that pneumonia is more common in Newcastle than is ordinary elsewhere, but it is obviously not correct now to attribute it, as I did, to the overcrowded and insanitary building.

Some of it results from the administration of anæsthetics, especially ether, and from the inability to cough, owing to pain in the abdominal wound. The day after the operation these patients have some difficulty in breathing, some cyanosis, moist râles over the chest, quick pulse, and elevated temperature. If their treatment is undertaken at once it is possible to put a sudden end to the whole trouble. The accumulated mucus must be got rid of by coughing, and this is effected by raising the patient up in bed, supporting the abdomen with strong arms and hands, and then encouraging vigorous coughing.

Some of it is due to septic inhalation from the mouth, nose, or throat, and develops usually during the first week after operation. It has become more uncommon since we paid more attention to mouth, nose, and ether inhaler sepsis, and to prevention of the inhalation of vomited matter.

For the greater number of cases no satisfactory explanation has been found. The only suggestion I have now to offer is that the "change of air" in the infirmary has something to do with it. In the majority of Northumberland and Durham poor-class homes coal is so cheap that the fire in the kitchen is *never* out night or day. At night especially this room, with beds in it, approaches the temperature of an oven, while in the well ventilated wards of the infirmary it is but little warmer than outside.

It is the exception for these patients, unless very feeble, to die from their pneumonia.

Cystitis.—Since the use of catheters after operation has become infrequent, and house surgeons and nurses have known that they would be blamed should cystitis occur, this has become a rare event. It is fortunate, as I have known one patient who made an excellent recovery from operation for strangulated hernia, and another who had undergone a most successful perineorrhaphy, made chronic and apparently life-long invalids through post-operative catheter cystitis.

Intestinal obstruction.—Adhesions may form after any abdominal operation, and adhesions are the most common cause of intestinal obstruction, therefore after every such operation the possibility of their occurrence should be kept in mind.

The cases most likely to be concerned are those in which a local peritonitis was present before the operation—e.g., appendix abscess, or ovarian cysts with twisted pedicle—and it occurs with greatest frequency during the second or third week, when recovery seems to be assured.

I have already[8] drawn attention to the very great importance of early diagnosis and prompt treatment in this condition, because the evidence I have offered strongly favours my belief that all of these cases can be saved by an early operation, and that delay means death. If the trinity of signs—(1) severe paroxysmal pain, (2) inability to pass flatus, and (3) evidence of increased peristalsis—are present, the sooner an operation is performed the better. If there is doubt, one ounce of castor-oil, followed by an enema, is likely to clear it up by making the patient either worse or better, and so deciding for or against immediate operation.

Phlebitis.—One of the most disagreeable consequences of an abdominal or pelvic operation is femoral phlebitis. With extraordinary regularity it appears about the tenth day after operation, usually with a bad aching pain in the upper part of the thigh and extending down the leg, with a rise of temperature to 102° F., and with a feeling of decided illness, which lasts from a week to a month. Swelling of the whole leg soon follows. Rarely is the patient able to get about with any comfort in less than three months, and, as a rule, more or less serious traces of the trouble are left for the remainder of life.

A condition so serious surely deserves more careful study than it has yet received. The probabilities seem to be that it is due to sepsis, but it is certain that septic infection of the usual kind, and by the ordinary channels, has nothing to do with it, for it usually occurs in "clean cases which have healed straight away," rather than in such as are septic in the ordinary sense. The most strongly predisposing cause is anæmia from previous prolonged hæmorrhage, such as occurs in fibroids or cancer of the uterus, so that hysterectomy is one of the operations after which it may occur. The prognosis, so far as life itself is concerned, is good. However ill the patients may be it is rare for them to die.

It is also very rare in femoral phlebitis for clots to become detached and produce pulmonary embolism, possibly owing to the painfulness of the condition enforcing rest on the patient. So far as I have observed, pulmonary embolism much more commonly follows thrombosis of the saphenous veins or their tributaries than of the femoral trunk.

When the condition has occurred nothing does any good but rest. I believe that it may be prevented by rubbing the legs regularly and by exercising them several times a day in bed.

Parotiditis.—This is a very serious complication, though now comparatively rare. Its present rarity is due to the recognition of its cause—mouth sepsis—and to the use of means to prevent this.

Ventral hernia.—A certain percentage of patients—it should be a very small one—get a ventral hernia after abdominal operations. This may be unavoidable. It is so if the wound suppurates, it is so with fat muscular persons who are growing fatter, and it may be so with the wrecks of humanity who suffer from multiple hernia, proptosis of the viscera, and general laxity of all the tissues. The treatment is to cure, if possible, by an operation, and if not, to give support by means of a belt.

Where to operate.—So far as is possible, I operate only in a properly equipped hospital, because I *know* that the dangers of operation are many times multiplied if they are done at home. Painful experience has taught me that not only the avoidable mortality, but the avoidable accidents and complications in even a larger proportion are increased to an alarming extent by yielding to the patient's natural desire to remain at home. No statistics have, so far as I know, ever been offered to support the opposite view, and I think there are good reasons for this.

The objection has been advanced that the chances of a patient who is very ill are damaged by removal and the journey. Our statistics furnish a complete answer to this. The whole profession knows that the avoidable mortality following childbirth in home practice is more than double that in maternity hospitals. Is it not better that the public should be taught to hear truths through the profession, and take the responsibility of evading them, if they so desire, rather than that these truths should be "discovered" by them? It appears to me to be impossible to doubt that in this country in 25 years no woman will be confined, and no person have any operation done, except in a properly equipped hospital.

Newcastle-on-Tyne.

[6] In cyanosed cases I have seen improvement follow the introduction of one drachm of tincture of digitalis into the rectal injection.

THE NOBEL PRIZE.—On Dec. 10th at Stockholm the King of Sweden personally presented the Nobel Prize for medicine, chemistry, and physics respectively to Professor Allvar Gullstrand, Madame Curie, and Professor W. Wien.

VENEREAL DISEASE: ITS PRESENT AND FUTURE.

BY DOUGLAS WHITE, M.D. CANTAB.;
AND
C. H. MELVILLE, M.B., C.M. EDIN., D.P.H.,
LIEUTENANT-COLONEL, ROYAL ARMY MEDICAL CORPS.

(*Concluded from p. 1618.*)

HERE, then, is our problem. It has never been seriously faced. How are we to face it? Are we to follow the continental example and regulate the traffic in vice? Our answer must be an unhesitating negative. For a hundred years and more regulation in some form has been tried in most European countries. It was an old system, revived by Napoleon. It was not introduced to Russia till 1844, but from that date till 1888 it was universal on the continent. In Britain a similar system was partially introduced into military stations in 1864; it was twice amended, but public opinion became so hostile that by 1886 it was entirely done away. Opposition to it began in 1869, and the effects of this outburst of feeling in England have extended to the continent since that date. Italy followed suit in 1888; in most of the Swiss cantons regulation has been abolished, as it has also been in Denmark and Norway. All over the continent a great movement is on foot, which is bound soon to sweep away the system: in France, Germany, and Russia its days are numbered.

But since regulation—namely, restriction and compulsory examination of prostitutes—still finds favour here in some quarters, it is necessary that we should touch on this subject more fully. To begin with, we may state our opinion that regulation is wrong in principle and a failure in practice. Why is it wrong in principle? First, because regulation of any immoral traffic by the State is itself immoral. This is an objection of sound statesmanship, not of silly prudery. In regulation, certain duties are imposed on certain women, and the fulfilment of those duties implies the recognised right to carry on their traffic. The obverse of responsibility is privilege.

Secondly, the laws of regulation are unjust as between the sexes. The women are subject to pains and penalties while the men go scot-free. In justification it is alleged that the prostitutes are the source of all disease existing outside their ranks. For the most part this is true; but all these women have been infected by men. And the men must be regarded as primarily responsible, for it is the demand of men which creates the supply of women. But the system is as stupid as it is unjust. If you do not remove the infected men from circulation, who form the large majority of infected individuals, it is of no use to remove the women, either in this or in any other class of infection.

Thirdly, the system is unjust, not only between the sexes but between the classes; the lower or poorer class of women are penalised while the more well-to-do escape.

Lastly, apart from its unsoundness on the side of ethics and justice, the system of State regulation of vice is founded on a blunder. To combat disease it attacks prostitution. Now disease can be attacked as disease, but prostitution cannot be attacked as prostitution. Disease is due to one set of causes, prostitution to many. If all prostitutes were removed from London to-day their places would all be filled in a wonderfully short space of time. If you want to get rid of dandelions in your garden you do not go round cutting off their heads; you take them up by the roots. Prostitution is a noxious weed, which has for its roots moral, social, and economic conditions. Poverty is the cause which leads more than 50 per cent. of these women to sexual vice; it gives them a living. To many, indeed, seduction gives the start downhill; to others vicious surroundings, antecedents, parents, and relatives. But poverty is, beyond doubt, the chief factor.

With both sexes, overcrowding, which follows in the wake of poverty, leads—I had almost said drives—into promiscuous immorality. But, overcrowding apart, the main causes which operate with men are selfish wilfulness, false shame, ignorance, and alcohol. Wilfulness, because they go wilfully to satisfy their sexual appetite without thinking of the price that others must pay; false shame, because young men are ashamed to confess to their comrades sexual inexperience; ignorance, because there is a widespread view that chastity is prejudicial to health or induces sexual impotence—a most mischievous delusion; alcohol, because 80 per cent of venereal disease in man is contracted under the influence of alcohol, which numbs the higher faculties and leaves the blind physiological impulses unchecked.

Before you can suppress prostitution you must eliminate its causes; in time, we may hope they will be eliminated; but it is a long journey: in any case you cannot directly suppress prostitution; much less can you extirpate venereal disease by an attempt to suppress prostitutes.

For these reasons, then, we believe the principle of regulation to be wrong. Now for the practice. Can it be regarded as in any respect a practical success? No; it is a total failure. On this point the reports of the Brussels Conferences of 1899 and 1902 are eloquent. Professor Gailleton says: "It is absolutely no good." Professor Fournier, the eminent authority, who with Neisser opposes the abolition of regulation, can only say that "it does a little good"; while Pierson insists that whatever little good it does is far more than outweighed by its far-reaching evil effects. Moreover, the form of regulation which Fournier and Neisser desire is by no means the present system of "police des mœurs," but a form of scientific sanitary control. It is clear that at that conference no one could affirm the success of "regulation"; further, the comparison already made between England on the one hand, and France and Germany on the other, is not eloquent in favour of regulation, since in disease at least they have no advantage over us, who have no regulation.

Let us inquire into some of the causes that have made regulation a failure. When a girl first goes wrong, she does so, not as a regular prostitute, but clandestinely; in the first year of her irregular life she contracts disease; indeed, the age of maximum incidence in females is 18; so the mass of such girls, before the age of 20, are clandestinely spreading disease among their clients. In France it is believed that 66 per cent. of syphilis in females is contracted before the age of 22, and 7/8ths of all syphilis in prostitutes is the result of clandestine vice.

It might be thought that licensed houses would be at least relatively safe, and it is claimed that this is so in Paris; but there is much evidence in other capitals pointing in the opposite direction. From syphilis at least we should expect most of the women to be free, having already had it, since under most circumstances it is impossible to take syphilis twice; but unfortunately there seems no doubt that a woman, free herself from infection, may still act as a mediator of contagion, harbouring within her own body the germs which, harmless to herself, will yet infect another; so the disease may be carried by a woman who is herself without symptoms. Even apart from such considerations no medical man can, on the ground of ordinary inspection, give a guarantee that any woman is free either from gonorrhœal or syphilitic infection.

Hence the licensed houses engender in the individual a false sense of security, while from the national point of view they only deal at best with one-eighth of the disease. Add to this that the licensed house is not popular. As the stringency of regulation increases so do the numbers of houses and their inmates decrease. In Paris to-day the number of licensed houses is less than 50, while in 1860 there were 200; in the same period clandestine vice has more than doubled in volume. As for the character of these houses, we are told that they have two main uses: to supply the first debauch of the young man, and the later bestialities of the *roué*.

Thus from every point of view, whether individual or national, whether moral or physical, whether of theory or practice, the weight of all evidence is against the State regulation of vice. It has been tried for a century and failed. At the best it is an outworn system, dating from a time when the nature of venereal disease was unknown, its long persistence unsuspected, and its terrible consequences not even dreamed of, while in the interval economic conditions also, specially in regard to women, have so altered that sexual vice at the present day furnishes a different and more complex problem. Thus it is undesirable, as in view of public opinion it is impossible, that State regulation should be established in this country.

Prostitution is an evil of which no Act of Parliament will ever rid us; its roots lie deep in the moral, social, and economic conditions, which are only capable of very gradual

improvement. But with venereal disease the case is widely different. Venereal disease is not synonymous with prostitution; syphilis, for instance, was not with us till Columbus discovered America in 1492. It is a contingent evil, not a necessary one; as it came quite lately in the history of European prostitution, so it may disappear long before that history is closed. But if this result is to be obtained we must treat disease as disease, since it is disease that we wish to combat, and not, according to the older fashion, treat prostitution as a crime. We must strive to eliminate venereal disease on the same principles as we seek to destroy other infections, adopting such methods as are specially appropriate to its peculiar character.

There are, however, certain popular objections against launching a campaign of extirpation against venereal disease, and in dealing with these we shall define our moral attitude on the subject.

The first is that such diseases come as a divine retribution for self-indulgence. This will not bear examination. Divine retribution must be self-consistent. Now in the case of syphilis such retribution was not instituted, in Europe at least, till the end of the fifteenth century, and 400 years is but a page in the history of vice. Divine retribution must be just in its incidence. But these diseases fall on the innocent and guilty alike—innocent wives, innocent children, innocent doctors. Of all women who suffer from syphilis, according to Fournier, 20 per cent. have taken the disease innocently from their husbands; Schrank considers the proportion higher in Vienna. In gonorrhœa the proportion is about the same. In the case of married women with syphilis, 95 per cent. contract it innocently from their husbands (Blaschko). In such marriages the first child (Fournier) is always fated to death in the first year of life, if ever it comes to birth at all; of all children of such parents 50 per cent. suffer the same fate; some of the later offspring may be free of disease; if they are not so they may even hand it on to the third generation. Syphilis may also be innocently contracted by social, apart from sexual, contact, by a kiss, or by common use of many ordinary utensils. Doctors are often infected while discharging their proper duties. Infants infect wet-nurses, and nurses children. Such is the condition of syphilis of the innocent to-day—less terrible now than in former years, when the initial virulence was greater than to-day, and less terrible than in Russia at the present time.

In the case of gonorrhœa, which is so lamentably common in towns abroad as to be almost universal in men before 30 years of age, the young husband frequently transfers it to his wife, who in consequence is liable to disablement, sterility, or even death. If there be a child, it is liable to infection of the eyes at birth, which unless promptly dealt with, may result in total blindness. In Prussia 30,000 such blind persons are to be found. Children also are not infrequently infected about the genitals by infected linen, and are liable to have their health and career ruined.

On the whole, we may say that about 8 per cent. of adult venereal disease is innocently contracted, as well as all venereal disease in children. How can these things be regarded as an exhibition of retributive justice? From Abraham onwards good men have recoiled at the idea of God punishing the innocent with the guilty. The Book of Job, 2500 years ago, forcibly rejected the idea of disease as the vengeful visitation of God; the later prophets rejected it; and the greatest of all Teachers refused to admit disease as representing divine retribution.

But, authority apart, no one can look on syphilis and gonorrhœa day by day and still adhere to the hypothesis of retributive justice. If it were true, we ought to refuse to cure the disease, except where the divine justice had plainly miscarried; but I think no such hardened mediævalist exists. Even for those whom we call guilty, the vast majority being girls from 16–23 and boys from 18–25, is it common justice that their lives should be blasted for an early—often the first and only—act of ignorant, procacious folly? I defy any man who is conversant with such things to say that the punishment fits the crime. We need not condone the offence to stand aghast at its result. If, then, we admit the cure of venereal disease at all, it is our bounden duty, both in logic and morals, to press forward by all proper means, not only to the diminution of vice, but to the extirpation of disease.

But again the objection comes: If vice is made safe from disease, it will increase by leaps and bounds. This we believe to be pure fancy. Did vice decrease when the monstrosity of syphilis made its sudden and appalling invasion? Is there any reason to think that, if venereal diseases were destroyed to-day, there would be an increase of vice to-morrow? We believe not. Few, if any, people are restrained continuously from vice by fear of disease. Partly, no doubt, because they are ignorant of the facts; yet venereal affections are by no means unknown among advanced medical students. And if fear or knowledge could act as deterrents, both fear and knowledge are drowned in alcohol, the almost invariable companion of illicit sexuality. Fear of disease may act as a reinforcement of higher moral considerations, but can never become a substitute for them.

"Go and sin no more." The words may serve to recall to our minds the true principle. First cure, then reformation. The healing of disease is among the most powerful weapons in our moral armoury; conversely, it is true that persistent venereal disease is, specially for women, the most insidious enemy of moral reform. There are, we are told, in the United Kingdom 284 rescue homes for women. These do excellent work; but they do not deal with *diseased* women. Diseased women have little chance of reform, though it is only by bad luck that they are in a worse position than their more fortunate sisters. Disease and its stigma are too often the chain which binds women to the life of vice, while its cure will often restore the dormant self-respect. On these grounds we reject the view of disease as a wholesome moral corrective, not only as untrue, but as the exact reverse of truth. We have spoken at length on these two ideas—disease as retributive and fear as deterrent—because we believe them to be radical errors, plausible and popular, no doubt, yet errors; which unless removed will, like suckers on the rose, sap away vitality from the tree of effort and prevent it blossoming into vigorous action.

Agreed, then, that we must attack these diseases directly, not to the exclusion of, but in addition to, other means of moral improvement. How are we to set about it?

First of all, we must have accommodation. As regards beds for such patients as need them, the general hospitals cannot and do not, as a rule, take them in. The Lock Hospital in London has 136 beds for females, and 27 for males; other lock hospitals elsewhere have about 70—possibly 250 in all. This cannot even touch the fringe of our needs. And the charitable public will not subscribe to the cure of venereal illness; it must be done by the State. Certainly a large proportion can be treated, and even efficiently treated, as out-patients; but the general hospitals, which are best suited to this purpose, have no special accommodation or special arrangements, such as are imperatively required for properly dealing with these diseases.

Each general hospital, then, should have special wards, and special arrangements in the out-patient department. Since we wish to attract patients to their own cure, all treatment should be free to all patients, the expense being borne by the State. Suitable hours should be arranged so as to attract patients without the loss of a day's work. For this purpose also dispensaries should be provided with suitable apparatus. In all such places measures must be taken to ensure privacy, decency, and self-respect; in particular, privacy from other patients should be secured.

As regards the medical staff, there should be a special course in venereal diseases and their treatment, with a special certificate attached, which should be required for any such appointment. As in the army, so in the civil service, this would lead to the treatment of these ailments being both effectual for the patient and honourable for the doctor. Printed instructions, calculated not to disclose to others the nature of the disease, should be given and read aloud to each patient, so that he shall certainly understand them. Proper appliances should be at hand, so as to commence and teach the required treatment. The sanatoriums which are now in contemplation should have their use extended to venereal disease. Many cases require such treatment. These ailments are certainly not less important to the nation than tuberculosis.

Before leaving the question of hospital reform and extension, we ought to mention the cure for syphilis known as salvarsan, or "606," recently introduced by the genius and labour of Ehrlich. This, so far as our best information goes, is destined to play a leading part in the arrest of syphilis. It offers a definitive cure by means of

one, two, or three injections, but it has its limitations and its necessities. Limitations, in that cure becomes less certain, and less immediate, in proportion as the disease has by neglect got a stronger hold on its victim. In other words, the patient must come without delay for cure at the first sign of infection. (This holds equally true of gonorrhœa; though the methods are less specific, they are fairly certain to cure if undertaken early and vigorously.) Our necessity lies in the direction of accommodation. The new treatment involves intravenous injection, after which the patient has to be under supervision for at least one night. If every hospital had a special ward, this need would be met.[1]

But how shall we get the patients to come for early cure? The only way that I can see is to offer free treatment, respect of privacy, and efficient attendance. Some will ask, Why not place venereal diseases in the same category with other notifiable infections? This cannot be done to its full extent, inasmuch as these infections differ from others. No one is ashamed of having scarlet fever, small-pox, or typhoid, but here it is otherwise. Notification in the full sense—communication of name and address to the authorities, who in their turn see that the patient is treated—is not practicable. It would certainly lead to concealment by the patient, and would hardly even command the assent of the profession.

But notification without names we must have. It is the only way of finding out the strength of the enemy. We should then at once begin to know our position and be able to form an estimate of our progress. At present we are simply floundering. Notification of this sort would not frighten the patient away nor wound the doctor's conscience. It would give us no immediate hold over the patients, yet if it were found that a large proportion were not submitting to effectual treatment, some method might then be devised for enforcing it. But at the outset, until public opinion forms, we must set our faces against any scheme which would frighten away the very people whom we wish to attract. This idea of nameless notification is not a new one. It has been variously adopted in Denmark and Norway, in Vermont and California; a Bill to the same effect is introduced now in New Zealand. If these methods were adopted we should be on the way to fighting venereal disease effectually.

But this is not all. We have other enemies. Foremost is the quack, who has a vast *clientèle*. Treatment of venereal disease, actual or suspected, by any but a registered practitioner should be made a penal offence; all advertisements of cure should be rigorously suppressed. In venereal disease there is no place for fancy cures; they are every way to the public detriment.

That persons afflicted with venereal disease should come early for treatment, implies a certain knowledge and understanding on the part of the general public. Such understanding is, in this country, at a lamentably low level. Boys and girls grow to puberty in complete ignorance of the physical facts of life, of the functions which in their bodies are coming to maturity. During this stage, for both sexes, ignorance means misery; and while they do not care, from natural reserve, to consult their parents, the parents in turn are generally too ignorant, even when asked, to give the needed information. Later on, when forewarned would mean forearmed, as soon as blind sexual impulse drives to indiscretion, there follow, not only regret and remorse, leading back to virtue, but blighting disease which aggravates, not heals, the moral wound.

Boys and girls as they attain puberty must be taught the elements of reproductive activity in plants and animals, leading up to that of the human species. At every technical, secondary, and public school they should receive lectures from properly qualified persons. They must be taught that personal chastity has no disadvantage, either for the sexual organs or the body as a whole; that this alone will fit them to be good husbands, good fathers, good citizens. Similarly public lectures should be given in all towns, teaching the populace generally the value of chastity and the dangers of disease, striving to raise, not only intellectual standards, but also moral tone, and inculcating the imperative call for early treatment on the first suspicion of disease.

By these means both the prevention and cure of venereal ailments could soon come within reach. Many other means are suggested which for the time being do not command our approval. The raising of the age of consent, in itself a desirable thing, would probably quickly prove a dead letter. Others demand universal certificates of health before marriage; before this could be effected there would have to be a public demand for such legislation; at present we must depend on voluntary action. The parents of every girl should obtain thorough assurances that their future son-in-law is free from venereal disease; ignorance alone stands in the way of this most necessary precaution. Lastly, as regards compulsory detention in refractory cases, some means could be found at a later date of compassing this end; but at the outset it would have the double danger of being inoperative on the one hand, and of frightening away the patients on the other.

A summary.—From its character venereal disease is a danger to every nation in which it is prevalent. Gonorrhœa lowers the birth-rate, as well as brings disaster on its victims. Syphilis is a terrible and insidious disease, causing huge infantile mortality and ruining the lives of many of the survivors. In the army and navy its incidence is known, and enlightened and successful methods for its diminution are being pursued. As to the civil population we have no information and no policy. No policy, however, is better than a bad or immoral policy. We must in no case adopt State regulation, which is both unjustifiable in theory and futile in practice.

As to the magnitude of the problem, an estimate has been given you of 200,000 fresh cases annually for London and half a million for the United Kingdom. The meaning of this latter figure will take shape in your minds when you consider that if this number of persons were put shoulder to shoulder, two feet for each person, this wretched army would cover a length of 190 miles, or more than the distance from London to York.[2]

If we are to face this business we must treat the disease as disease; we must abandon outworn philosophies of divine retribution and fantastic fears that decrease of disease will spell increase of vice. Banish these false thoughts which kill enthusiasm. We must set about to cure these plagues, not, as at present, grudgingly and of necessity, but heartily and of set purpose.

To this end it is suggested that there should be reform in hospital accommodation, both in- and out-patient; that members of the special staff should have special training; treatment should be free to all and at convenient times, with adequate provision for up-to-date methods; public ignorance in these matters should be remedied by all possible means; the quack and all his works should be suppressed; and lastly, notification should be insisted on, without names indeed, but with a full account of age, sex, date of infection, duration of treatment, and result thereof. At first there would be an apparent increase in the number of patients, but this would soon give way to decrease, and with a decrease in disease there would be a decrease of vice.

The present time is favourable for the commencement of a campaign against venereal disorders. Gonorrhœa can be cured in its early stages, and its present incidence might be enormously diminished; against syphilis we have in our hands a specific, by means of which, rightly used, this disease might in a short time be eliminated. If full advantage were taken of these facts the economic and, as we think, the moral gain to the community, resulting from the diminution of disease, would quickly, amply, and repeatedly repay the cost of such an effort, for which the means are at hand and the time is ripe.

[1] On this whole subject see "Syphilis" by McIntosh and Fildes. Edw. Arnold, 1911

CASE OF RAPID INVOLUTION OF A UTERINE FIBROMYOMA AFTER PARTURITION.

BY REGINALD L. E. DOWNER M.B., B.S. LOND., M.R.C.S. ENG.

THE following case, showing, as it does, the total spontaneous disappearance of a fibromyoma of the uterus, is of some interest.

The patient, aged 25 years, was expecting her first child, and on the first occasion that I saw her was already in labour. The fœtus was in the first vertex position, but a somewhat puzzling tumour was present in addition, situated at the uppermost part of the fundus uteri, fairly mobile, hard, smooth, dull to percussion, of the size of a cricket ball, and

[2] The Hon. Sydney Holland will pardon a plagiarism.

suggesting at first sight some kind of monster or fœtal abnormality. Labour proceeded normally, however, and the patient was delivered of a healthy child. There was no post-partum hæmorrhage, and no difficulty with the after-birth. As soon as the uterus was empty, and contraction and retraction were well established, I was able to devote attention to the tumour, which retained all the characteristics previously noted.

As I saw the patient day by day, the uterus descended into the pelvis, and the puerperium was uneventful. The tumour sank with the uterus, and maintained its relative position thereto. It could be moved to a small extent over the uterus, and one could feel that it was attached to it by a short thick pedicle. Moreover, it steadily shrank, so that by the tenth day, when just above the symphysis pubis, it was no larger than a golf-ball. Ten days later it could be felt bimanually only, and was smaller still.

The patient was rather concerned about the presence of the swelling, which she herself had been able to feel during the early days of the puerperium, and which was a little tender on manipulation, but I reassured her, and promised to examine her again later. About two months after labour, therefore, I saw her. Nothing abnormal could be felt per abdomen. Per vaginam the uterus was anteverted, and the sound, with concavity forwards, passed 2¾ inches. Bimanually the uterus was felt to be a little thickened, but no tumour of any sort could be discovered. The patient was in excellent health and very relieved to hear that the swelling had departed.

I take it that the tumour I had originally discovered was a subserous pedunculated fibromyoma of the uterus. It was not composed of fæces, for it had not the consistency of these, and a fæcal tumour would hardly descend and shrink *pari passu* with the uterus. Another rare kind of swelling found in connexion with the uterus during labour (but easily and immediately excluded in the present case) is that due to the extrusion of a fœtal part after uterine rupture.

The condition as felt after the birth of the child suggested the signs that one might expect in that very rare condition hour-glass contraction of the uterus, but the persistence of the tumour after the birth of the placenta and the absence of post-partum hæmorrhage would have been sufficient to dispel such a notion, even had the condition during the earlier stages of labour not been observed.

One is forced to the conclusion, then, that a fibroid of the size of a cricket ball entirely disappeared in the course of two months during the process of involution. This, I imagine, is a very rare eventuality, but it does occasionally happen, and as Haultain[1] says, "This happy result is probably attained by firm uterine contractions impairing the blood-supply of the growth, and causing a degeneration of the muscle fibres analogous to that which occurs in the normal puerperal involution."

A year later the patient again became pregnant, and at the present time, gestation having proceeded for five months, there is no sign of any reappearance of the tumour.

Woking.

THE USE OF CALCIUM SALTS AS A PROPHYLACTIC AGAINST SERUM RASHES.

BY MAURICE A. CASSIDY, M.A., M.D., B.C. CANTAB., M.R.C.P. LOND.,

PHYSICIAN TO OUT-PATIENTS AND LATE RESIDENT ASSISTANT PHYSICIAN, ST. THOMAS'S HOSPITAL.

IN the diphtheria ward at St. Thomas's Hospital it has been the custom during the last few years to administer calcium salts with the object of influencing the severity of antitoxin rashes. In order to ascertain the effect, if any, of this treatment, I took 62 consecutive cases and administered calcium to alternate ones, irrespective of the extent of membrane or dose of serum. The chloride was the salt used in most cases, but the lactate was given occasionally; the average dose was 5 gr. (maximum, 10 gr.; minimum, 3 gr.), given three times a day, omitting every third day. These doses may be considered small, but it must be pointed out that only 8 of the cases were more than 10 years of age. In each case rashes were carefully looked for, and, when present, noted as being "faint," "moderate," or "severe." Of these 62 cases, 12 died in less than 12 days after admission, and are therefore excluded. The results observed on the remaining 50 cases are tabulated below.

[1] Allbutt, Playfair, and Eden: System of Gynæcology.

Age.	Total dose of serum.	Dose of calcium.	Rash.
4	5,000	10 gr.	None.
6	8,000	None.	,,
5	26,000	5 gr.	Moderate 17th and 18th days.
4	14,000	None.	Faint 7th day.
3	24,000	5 gr.	Faint 8th day.
3	18,000	None.	Faint 13th day.
7	8,000	5 gr.	Moderate 8th and 9th days.
1	28,000	,,	Severe 5th to 11th day.
3	12,000	None.	None.
2	16,000	,,	,,
25	16,000	10 gr.	Severe 9th and 10th days.
25	20,000	None.	None.
26	24,000	10 gr.	Severe 7th to 11th day.
5	26,000	None.	Severe 9th to 14th day.
2	20,000	5 gr.	Moderate 14th to 16th day.
5	26,000	None.	Faint 7th to 9th day.
13	12,000	8 gr.	Faint 9th to 11th day.
2	14,000	3 gr.	Faint 12th day.
4	12,000	None.	None.
6	20,000	8 gr.	,,
1	14,000	4 gr.	Severe 7th and 8th days.
2	6,000	None.	None.
2	6,000	5 gr.	Severe 6th and 11th day.
5	12,000	None.	None.
6	6,000	5 gr.	Faint 6th and 7th days.
1	6,000	None.	None.
4	6,000	5 gr.	,,
1	6,000	None.	,,
25	12,000	,,	Moderate 7th to 12th day.
3	24,000	5 gr.	Moderate 8th to 12th day.
4	2,000	None.	Faint 6th day.
6	20,000	,,	None.
5	2,000	,,	,,
6	2,000	,,	Faint 7th day.
3	2,000	,,	Faint 8th day.
1	20,000	4 gr.	Severe 8th to 11th day.
1	2,000	None.	None.
5	8,000	5 gr.	Moderate 7th and 8th days.
19	12,000	None.	None.
10	14,000	5 gr.	,,
2	22,000	,,	Severe 12th to 14th day.
2	2,000	None.	Faint 4th to 6th day.
22	16,000	,,	None.
5	20,000	,,	,,
1	8,000	3 gr.	Severe 8th to 11th day.
7	12,000	None.	Severe 6th to 14th day.
5	12,000	,,	Severe 6th to 14th day.
4	26,000	5 gr.	Faint 7th to 9th day.
5	20,000	,,	Faint 8th day.
1	8,000	3 gr.	Severe 8th to 11th day.

The above table may be summarised as follows:—

—	Average dose of antitoxin.	No rash.	Faint rash.	Moderate rash.	Severe rash.	Average duration of rash when present.
23 cases treated *with* calcium ...	16,000	4	6	5	8	8·4 days.
27 cases treated *without* calcium	11,000	16	7	1	3	3 days.

Calcium chloride is a nauseating drug and it is difficult to persuade children to take it; further perseverance in this direction would seem to be unnecessary if the above figures are to be trusted. I am indebted to the physicians of St. Thomas's Hospital for permission to publish these figures.

Queen Anne-street, W.

A DIPLOCOCCUS FROM THE URINO-GENITAL TRACT.

BY LEONARD S. DUDGEON, F.R.C.P. LOND.,
BACTERIOLOGIST TO ST. THOMAS'S HOSPITAL, AND JOINT LECTURER ON PATHOLOGY IN THE MEDICAL SCHOOL;
AND
P. N. PANTON, M.A., M.B. CANTAB.,
CLINICAL PATHOLOGIST TO THE LONDON HOSPITAL.

THE organism we describe in this communication is one which is not infrequently met with in the urino-genital tract, yet appears to have escaped notice in the standard works on bacteriology. It is a diplococcus in no way allied to the pneumococcus, yet the two organisms may be, and indeed have been, confused.

Distribution.—We have isolated the organism from the urine of women, children, and much less commonly male adults, as well as from the vagina, and we have obtained pure cultures of it from pus from the interior of the uterus. It appears to be particularly common in the urine of small children; in an examination of carefully taken catheter specimens from 11 children with epidemic diarrhœa we met with it in 8 cases.

Morphology.—The organism appears in films from the tissues as a diplococcus. It may be present in the pus in enormous numbers, and is readily taken up by the leucocytes. In broth media it is found in pairs and short chains. Lanceolate and bacillary forms are very common both in solid and liquid media. The organism retains the stain by Gram's method. Neither in the tissues nor in cultures have we seen any appearance of a capsule.

Cultural characters.—Serum agar, agar slopes, and agar plates gave translucent pin-point colonies of the streptococcal type. The colonies are frequently somewhat coarser in the first cultures on agar plates, the subcultures yielding a profuse growth of very delicate colonies. Gelatin slope gives a profuse growth without liquefaction. Broth yields a general turbidity. Litmus milk is turned acid and completely decolourised in 24 hours, while we have observed this change to occur in six hours. A solid clot is generally formed in about three days. The complete and rapid decolourisation of litmus milk is the most noticeable and constant cultural characteristic. Neutral red broth is unaltered by some strains, while others produce a green fluorescence. Litmus salicin, dextrose, lactose, mannite, maltose, and saccharose are all acidified in from 24 to 48 hours. Litmus raffinose remains neutral for 24 hours, but as a rule becomes decolourised later. His's serum inulin medium is unaltered, but the organism grows well in it. The coccus grows abundantly on subculture, on all the ordinary media, and retains its vitality. An agar culture kept at the laboratory room temperature for three months grew readily on subculture and gave all its original cultural characters.

Pathogenicity.—The organism may be present in the urine without other evidence of disease. In one case it was obtained in pure culture from the urine of a man, aged 25, with a pyonephrosis and abundant pus in the urine. In another case it was the sole organism found in the persistent cervical discharge of a woman suffering from peritonitis who recovered without surgical interference after treatment by a vaccine prepared from the coccus.[1] The agglutination test performed with the sera of two patients from whom the organism was isolated was in both instances negative.

The following inoculations were made into animals. A suspension of 3 c.c. of normal saline solution was made from an agar culture. Of this 0·5 c.c. was injected intraperitoneally into each of two mice. One mouse became ill and was killed in 24 hours, the other died suddenly ten days later. No evidence of disease was found in either animal, but the organism was recovered from both in pure culture from the blood stream and from the peritoneum. Two c.c. of the same suspension were injected into the vein of a rabbit and no effect was produced. A third mouse was inoculated with the organism recovered from the first mouse without ill-effect; it was killed four weeks later, but the coccus could not be recovered from the tissues.

Remarks.—In its staining properties, its morphological appearances, and in the nature of its colonies on agar this organism closely resembles the pneumococcus, yet in every other respect the two bacteria are widely different. It should hardly be necessary to insist that the diagnosis of a pneumococcal infection can only be made after full cultural and other investigations, yet we venture to thiuk that the frequency with which the pneumococcus has been reported from the urine and from vaginal discharges depends upon the mistaken identity of that organism with the one we have described; in fact, we have evidence that this mistake does occur. The organism is one not infrequently met with, and may be unaccompanied by any evidence of disease. In a certain proportion of cases, however, it is associated with the ordinary phenomena of inflammation and may be the sole organism detected. The coccus appears to have little or no pathogenic action on mice or rabbits.

[1] The husband of this patient suffered from a urethral discharge, but evaded, possibly unwisely, a bacteriological examination

SPLENOMEGALIC POLYCYTHÆMIA WITH CYANOSIS.

(OSLER'S DISEASE OR MALADIE DE VAQUEZ.)

BY E. CLARK-JONES, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE SENIOR HOUSE SURGEON, EVELINA HOSPITAL FOR CHILDREN, ETC.

A CASE of this extremely rare disease is worthy of record.

In March of this year I was called to attend a patient aged 56; he was stated to be suffering from "a cold on the chest." At first sight the thing that at once struck one was the patient's extreme cyanosis. The lips and ears in particular were nearly black, and the whole countenance was livid. The patient was seated comfortably in a chair, and instinctively one felt, without being able, perhaps, to trace the steps of the mental process, that one was face to face with something that did not "fit in" with any ordinary condition.

The respirations and general demeanour of the patient at once put out of court any suggestion of acute respiratory or cardiac trouble. The cyanosis was not the distinctive colour of that of congenital heart disease, which, so far as I know, is simulated by no other pathological condition. Advanced emphysema, although we know it may be accompanied by extreme cyanosis and comparative comfort, was negatived by the obvious absence of anything approaching an emphysematous shaped chest. One could see at a glance that there was no clubbing of the fingers.

The patient's immediate history was unimportant. He resided on the south coast, and had been in town for two or three weeks' change. Some days before he had caught a cold which had settled on his chest. He was spitting up some mucus. His past history was as follows. For many years he has suffered from migraine. The attacks were very severe and prostrated him for two days at a time. Fifteen years ago he had some œdema of one ankle and leg, and consulted Dr. Frederick Taylor for that and the migraine. Dr. Taylor told him that he was sound organically, and under treatment the œdema disappeared and he derived marked benefit so far as the migraine was concerned. About nine years ago he consulted the late Dr. J. F. Payne, who corroborated what Dr. Taylor had said. Some two or three years later he again saw Dr. Taylor, who examined him and pronounced him free from organic disease. Up to six or seven years ago, then, we are justified in assuming that the present disease had not manifested itself.

About four years ago he had a sudden attack of vertigo and lost consciousness for about one minute. At intervals since he had occasionally felt giddy, but had never again "lost himself." For several years his friends have been remarking that he was getting "a better colour," having previously been pale in complexion. His life has been regular and his habits abstemious. He does not smoke. Beyond coughs and colds occasionally, he has had no other illnesses, and up to the time of my seeing him had not the remotest idea that anything was wrong. To slight dyspnœa on exertion and so ne constipation he paid no attention. The patient had never been abroad.

On examination there was general cyanosis, most marked in the ears and under mucous membranes. The gums, tongue, pharynx, and inside of the mouth generally were of a deep purple colour. The gums bled with extreme ease,

and when the patient coughed a little blood came with the expectoration, but was not really mixed with it, and obviously emanated from the pharynx. The conjunctivæ were deeply injected.

Chest.—Lungs normal. There was no emphysema, which must be emphasised in view of the nature of the case. A few coarse rhonchi were heard, but beyond this nothing abnormal.

Heart.—The upper limit of dulness was at the third rib. To the right it did not encroach beyond the right edge of the sternum. The apex beat was in the fourth space just internal to the nipple line. The dulness extended beyond the region of the apex and was of great extent, passing out to the mid-axillary line. In view of the position of the beat being in the fourth space and internal to the nipple line the suggestion was that the heart was pushed up from below, and that the dulness beyond the nipple was caused by some organ other than the heart. A soft systolic murmur was heard at the apex, but there were no symptoms arising from it.

Abdomen.—Having found nothing in the chest to account for the cyanosis, one next examined the abdomen. The right side was flaccid and nothing abnormal was felt, but the left side was very rigid apparently. This rigidity was soon proved to be due, not to the muscles, but to an enormously enlarged spleen which extended forwards to the middle line, backwards into the flank as far as the posterior axillary line, and downwards nearly to the pubes. The notches could easily be felt. There was no tenderness, and the surface was smooth, firm, and unyielding. The edge was quite hard and sharply defined. The patient had not the remotest idea that there was anything abnormal about his abdomen.

This cleared the ground considerably. It was obvious that the symptoms and physical signs were not satisfactorily accounted for by one disease. The patient had a chronic disease, almost certainly intimately connected with the spleen, and the cough and cold were an independent and transitory affection in no way related to the cyanosis.

Nervous system.—There was no evidence of organic disease. The knee-jerks, plantar reflexes, &c., were normal. No anæsthesia existed.

Circulatory system.—The radial was slightly thickened, but not beyond the limit of health for a man of the patient's age. The blood pressure was 140–160 mm. Hg. The flow of blood was sluggish, the viscosity being increased.

The urine contained a faint trace of albumin.

Blood examination.—This was carried out on two occasions, the second being used as a check on the first. The two reports were substantially the same: hæmoglobin, 110 per cent.; red blood cells, 8 500,000 per c.mm., or 170 per cent.; color index, 110/170—0·6; white blood corpuscles, 20,000 per c.mm. The red cells were moderately regular in size and shape, the average diameter being about 8μ, and poikilocytes not being seen. The stain was moderately well retained by the cells, while abnormal staining and nucleated forms were not seen.

A differential count of white corpuscles gave the following results: polymorphonuclear neutrophiles, 92 per cent., or 18,400 per c.mm.; small lymphocytes, 6 per cent., or 1200 per c.mm.; large lymphocytes, 1·2 per cent., or 240 per c.mm.; eosinophiles, 0·8 per cent., or 160 per c.mm. Mast cells and myelocytes were not seen.

There was thus evidence of a polycythæmia with marked polymorphonuclear leucocytosis, accompanied by great enlargement of the spleen and marked cyanosis.

I had never before seen a case, and explaining the ascertained facts to the patient I suggested that we should have a consultant to see him before he returned home. He agreed, and Dr. Herbert Hawkins visited him. I explained to Dr. Hawkins exactly what I had found on examining the patient, and directly I showed him the blood report he expressed his opinion that the clinical and microscopical examinations supported each other, and he identified the disease as Osler's splenomegalic polycythæmia with cyanosis. His subsequent examination of the patient confirmed his view. Dr. Hawkins had seen two cases, one of which was under his care and the other under Dr. T. D. Acland. Concerning treatment, he had found systematic bleeding unsatisfactory, and as the patient would be returning home as soon as his temporary trouble was over, it did not appear to be worth the trial. I had been giving the patient iodide, and Dr. Hawkins suggested his taking it in the form of iodalbin, gr. v. t.d.s., for a month at a time with a week's intermission.

About ten days later the patient was able to return home. I heard from him at intervals. He was keeping well, carrying out instructions as regards food, drink, exercise, &c., and had had only one attack of migraine since March. I went down to see him in September and found that his health was good. The cyanosis was not so marked. The spleen was, if anything, *slightly* smaller, but there was no marked alteration in size. The cardiac condition was quite satisfactory. The murmur was giving rise to no symptoms. Any evidence of hypertrophy was extremely slight. The difficulty of accurately percussing out the cardiac dulness of course remained. *The lungs were perfectly normal.* I saw him again in October. His condition was still the same.

The condition is one of great interest. Unfortunately, treatment is of very doubtful benefit. The patients may go on comfortably for a number of years apparently, but the termination seems to be pretty certainly cerebral hæmorrhage. With regard to venesection, it would appear rational to try its effect should the blood pressure become dangerously high or the attacks of temporary unconsciousness frequent. I venture to suggest that this treatment would be likely to prove of more avail than the exhibition of nitroglycerin and its allies, *especially in cases unaccompanied by arterio-sclerosis.*

For the diagnosis of the disease Sir William Osler requires chronic cyanosis, polycythæmia, and enlargement of the spleen, and the absence of advanced emphysema and chronic heart disease. I believe that in all his cases included under the heading of this disease emphysema and chronic heart trouble were absent. A little discrimination is required here, however, because I believe it is a fact that as the disease (polycythæmia) progresses unequivocal and very serious cardiac lesions develop. A case might be rejected because of chronic heart trouble, while really the cardiac condition was the result of the blood disease. In an early case with a mitral systolic murmur, is the bruit of a hæmic nature?

With regard to the pathology of the disease, it appears to be pretty clear from the presence of normoblasts and megaloblasts that there is an active production of erythrocytes, and "some of the few post-mortems have demonstrated increase of the marrow, and one at least has confirmed Widal's view that the splenic enlargement is due to the resumption by the spleen of its fœtal property of production of erythroblasts" (Adami's "Principles of Pathology"). Dr. Parkes Weber says it is due to an "increased erythroblastic activity, involving a great part, but not necessarily, the whole, of the bone marrow." At any rate, what is *unknown* is the stimulus that stirs the bone marrow into increased activity.

The argument that the disease is due to diminished destruction of red cells seems to be generally regarded as a slender one. Large collections of disintegrated red cells have been found in splenic pulp, and in eight cases urobilin in the urine in sufficient quantities to suggest an excessive breaking down. The argument that the spleen fails in its function of destroying red cells consequently does not hold good. On the other hand, the evidence in favour of an increased formation of red cells is considerable and direct. In fact, "in every case of the disease in which the bone marrow has been examined microscopically it has been found that the yellow marrow, normally found in the long bones, has been transformed into red marrow relatively free from fat and showing active formation of red cells" (Mackey). Vaquez says that in every case of a true polycythæmia there is increased formation of red corpuscles, associated with continuous and frequently progressive increase of number in the circulating blood.

In a synopsis, by Dr. L. G. J. Mackey, of just over 40 recorded cases there are admittedly a considerable number that do not fulfil the required conditions which would justify their inclusion. Apart altogether from the many cases of *relative* polycythæmia from various causes, there are undoubtedly many cases of true polycythæmia from congenital heart disease, acquired valvular disease, especially mitral stenosis, adherent pericardium, &c., which may not be included under the heading of Osler's or Vaquez's disease. There must be (to repeat) true polycythemia, with enlarged spleen and cyanosis, in the absence of emphysema and chronic cardiac conditions. That there is such a condition is proved by the cases collected by Sir William Osler and others, each of

which, few though they be, conforms to the requirements laid down.

Clapham Park, S.W.

OVARIAN CYSTOMA OF UNUSUAL SIZE COMPLICATED WITH VENTRAL HERNIA AND ASCITES.[1]

BY H. MACNAUGHTON-JONES, M.D. Q.U.I., M.A.O., F.R.C.S. IREL. & EDIN.

THE following is a note of an ovarian cystoma of unusual size; it was the largest tumour of its kind I have ever seen. Possibly some of those present will have dealt with larger, and in patients of still more advanced age. I was indebted to Dr. W. C. Dowling Prendergast, of Hanley, for the opportunity of seeing the patient and for this short history of her condition antecedent to operation.

Age 67; married; no children; first noticed a swelling in the abdomen 12 years ago; has been under his care for 11 years (I may here interpolate that the patient determinedly refused to take the advice repeatedly given to submit to operation); has worn an abdominal belt for some years for a ventral hernia, and some four years since this latter increased in size and became very prominent. Her general health was fairly good; the bowels kept regular. The immediate cause of her submission to an operation was the huge size of the abdominal swelling, which prevented all attempt at locomotion. "The walls over the umbilical hernia were thinned to such an extent [Dr. Prendergast also says in his report] that he feared rupture of the abdominal wall."

The condition of the patient immediately before operation, when I first saw her in her own house, for she could not be removed, was not an inviting one, and I dreaded even her removal into an adjacent room prepared for the operation. She was under the influence of scopolamine-morphia which had been administered on the previous night and again that morning, and an injection of strychnine and atropine had been given an hour before. The anæsthetic was most skilfully administered by Mr. A. P. Square. The girth of the abdomen in the prone position by careful measurement at its greatest circumference was 57½ inches. The abdominal muscles for a considerable extent had separated and the wall was thinned out with a diffused rupture which included an area of several inches in circumference above the umbilicus.

The peritoneum was firmly attached in front to the sac of the cyst, and both, for some extent, were adherent to the abdominal wall. In detaching the peritoneum before puncture from the wall of the sac a quantity of ascitic fluid escaped. Dreading the effect on the anæsthesia through the sudden relief of pressure, the abdominal wall at either side was held well up and the remaining ascitic fluid very slowly drained off. The rest of the operation was simple. The huge cyst was emptied and removed, and the patient was in a good condition when placed in bed.

The operation was performed on April 21st, and on May 3rd Dr. Prendergast reported the patient as "full of life and spirits," and a fortnight afterwards she was in her garden daily. On Oct. 27th last he saw her, when she was "well and able to do her shopping."

Harley-street, W.

[1] A note read at a meeting of the Obstetrical and Gynæcological Section of the Royal Society of Medicine on Nov. 3rd, 1911.

LIVINGSTONE COLLEGE.—The annual report and statement of accounts of this college shows a decline in the number of students attending the college, with the result that there is now a financial deficiency of £500. It is hoped that this debt will be speedily removed, and that the result of the Livingstone Centenary Fund in connexion with the centenary of the birth of Dr. Livingstone, which will occur in 1913, will place the college in a better position. Twenty-seven students entered for not less than one term during the year. The report makes reference to the appointment of a board of missionary study, as a result of the World Missionary Conference held in Edinburgh last year, which it is hoped will lead to greater attention being devoted among other things to the necessity of elementary medical training for missionaries.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Exhibition of Cases.

A MEETING of this section was held on Dec. 8th, with Sir WILLIAM OSLER in the chair.

Mr. HERBERT TILLEY showed four cases illustrating surgical treatment of Chronic Empyema of the Nasal Accessory Sinuses. Case 1 was a male, aged 71, who sought relief for double vision, and complained of no other symptoms. A small, tense swelling was observed between the right eyeball and the inner half of the "orbital arch." There was distinct proptosis of the eye. Examination of the nasal cavities revealed a free discharge of pus from all the sinuses on the right side. At the operation an incision was made immediately below the right eyebrow and along its whole length, and terminating just above the internal canthus. The swelling above referred to was found to be part of the wall of the frontal sinus empyema, which by destroying the roof of the orbit had forced its way anteriorly. The anterior wall of the sinus was completely removed, when it was found that the whole posterior wall of the sinus had been destroyed, exposing a large area of dura mater, while the floor of the sinus consisted of the contents of the orbit. The right maxillary antrum, ethmoid, and sphenoid sinuses contained pus, and were freely drained by the usual surgical methods adopted for these bony cavities. The patient made an excellent recovery, with very slight deformity. The curious feature of the case was that in spite of the extensive destruction of the bony walls of the frontal sinus, he never suffered from headache, or complained of any purulent nasal discharge. His one trouble was "seeing double." The second case was a female, aged 30, admitted to University College Hospital in July, 1911, for inflammation of the "right eye and face" of five weeks' duration. On admission there were intense inflammation and swelling of the right side of the face, extending from the frontal eminence to the level of the right angle of the mouth. The right eye was proptosed and the globe hidden by swollen, œdematous, everted conjunctivæ. The upper eyelid was swollen, œdematous, and of a purple colour, and just below the inner angle of the eyebrow was a pus-discharging fistula leading backwards to the posterior and inner region of the orbit. A purulent discharge was seen in the right nostril and in the naso-pharynx. The temperature was 102° F. The mental condition was obtuse. The patient looked very ill. An operation similar to that in Case 1 was carried out immediately. A large collection of pus was opened on the inner side of the orbit and sequestrum removed from the posterior ethmoidal cell region. The antrum was opened in the canine fossa and found to be full of caseated pus; the inner antral wall was removed to provide for free and permanent drainage. The patient's recovery was retarded by symptoms of pleurisy, which eventually cleared up. Only slight deformity was to be noted in the region of the frontal sinus, in spite of free removal of all its anterior wall. The third case was that of a female, aged 13, who was admitted to University College Hospital for acute swelling and œdema of the left upper eyelid and lower frontal region. The temperature was 102° F. She had some headache and malaise. There was no discharge of pus from the left nostril and none to be seen in the left nasal cavity. The same operation was carried out as in Cases 1 and 2. About a drachm of pus was found between the eyeball and the lateral mass of ethmoidal cells. The frontal sinus also contained pus and was freely opened and drained. Rapid recovery took place, with little deformity. The condition was uncommon in children. The fourth case was a male, aged 60, whose left frontal sinus was opened from the outside because of severe headache associated with empyema of that sinus and the corresponding antrum. Killian's operation was performed—i.e., the anterior wall and floor of the sinus were removed, with the exception of that portion of the orbital arch which formed the junction of the wall and floor of the sinus. By leaving that bridge of bone very little deformity resulted, as was seen in that case.

Mr. H. MORRISTON DAVIES showed a case of long-standing Dislocation of the Patella (? traumatic) and Osteo-arthritis of the Knee-joint treated by operation 18 months ago. The patient was a widow aged 55. Forty-eight years ago she fell down and dislocated her right patella. Since then the patella had remained on the outer side of the knee. There was no history of poliomyelitis, and the electrical reactions did not suggest that the original dislocation was due to paralysis. Thirty years ago the patient began to be troubled with pain in the right knee, and ten years ago she was unable to stand or walk without the aid of a special splint and crutches. At the time of her admission to hospital in May, 1910, there was considerable genu valgum of both legs; the right patella was lying to the outer side of the joint with the anterior surface looking directly outwards. The condyles of the femur were easily palpated and marked osteo-arthritic changes could be recognised. With the leg fully extended it was possible only partially to replace the patella. The patient was unable to lift the limb off the bed or to extend it against resistance. There was considerable wasting of the quadriceps femoris, and especially of the vastus internus; the knee-jerk, however, was obtainable. The main steps in the operation, which was performed on May 27th, 1910, were:—1. The opening of the knee-joint and the removal of a large part of the anterior and inferior surfaces of the external condyle, so as to allow the patella to ride over the lower end of the femur when the joint was flexed. 2. The division of the extension of the quadriceps femoris on the outer side. 3. The freeing of tendons of the gracilis and semi-tendinosus muscles from their insertions in the tibia, and the stitching of the cut ends of those to the inner side of the patella. The tendons were passed under the sartorius and enclosed in folds of the capsule. 4. The longitudinal pleating of the capsule so as to tighten it on the inner side of the joint. Massage and passive movements were begun on the fourth day, but a fortnight later adhesions in the joint had to be broken down. On June 20th the patient could flex the knee to a right angle and could lift the leg off the bed. She left the hospital wearing only a bandage as support. The patient celebrated the first anniversary of her operation by going to a dance and dancing hard. She can now run up and down stairs and work all day long without pain or undue fatigue. The actual result from a cosmetic point of view might be still further improved by curing the genu valgum, but considering the patient's age and the satisfactoriness of the limb there was no indication for the further operation.

Mr. HENRY CURTIS showed a case of Acute Periostitis of Rib, with separation of sequestra (non-tuberculous, non-traumatic). The comparative rarity of the condition seemed to justify the record of the case. The patient, a Hebrew boy, aged 14, was admitted to hospital on March 31st, 1911, for pain in the chest. He first complained of pain over the heart, compared with the "sticking of needles," on the previous Monday, and it became steadily worse. On admission the facial expression was anxious, with a hectic flush on the cheeks, furred tongue; temperature 102·5° F., pulse 112, respiration 28. There was no constipation. The right chest, front and lower axilla, were fuller than the left, and slight but distinct œdema was observed, with widely diffused marked tenderness, which extended well over the contiguous upper abdomen, in the right hepatic region, where there was considerable rigidity. There was some loss of note over the right front below, but no abnormal breath sounds. There was a leucocytosis of over 20,000. A diagnosis of empyema or acute abdominal suppuration—e.g., subphrenic abscess—were possibilities, but exploration of the chest negatived empyema; a second needle puncture struck what appeared to be bare rib, evacuating pus. Following the needle down by an oblique incision downwards and forwards along the line of the fifth right rib pus was found welling out in large quantities from beneath detached, thickened, congested periosteum, between it and the rib. Free drainage was effected above and below. The wounds closed by May 17th, but two sequestra were removed on Sept. 19th, one from the upper one in the anterior axillary line, the second from the anterior wound in the parasternal line; the third, and largest, sequestrum was removed from the lower wound on Nov. 11th, both incisions now being soundly healed. The pathologist's report negatived tubercle, a pure culture of staphylococcus pyogenes aureus being obtained.

Mr. E. M. CORNER and Dr. L. GRANT showed a case of Healed Double Empyema in a male patient, aged 29, who was admitted with both pleural cavities containing pus to the Passmore Edwards Hospital, Wood Green, under the care of Dr. Grant, on Sept. 11th last. A rib was resected on the right side, as that side contained most fluid; three pints were withdrawn. On the next day (the 12th) 1 pint of pus was withdrawn by aspiration from the left side, and on the 13th a rib was resected on that side. The left side healed and closed in 11 weeks, the right side in about 10½ weeks. Since then the man had made steady progress, adding 3 lb. to his weight the week previous to the last time he was seen. His heart was still displaced and the pulse-rate was still rapid.

Mr. R. P. ROWLANDS showed a case of Anterior Gastro-jejunostomy, Perforated Jejunal Ulcer, Detachment of Jejunum, Excision of Ulcer, Gastro-duodenostomy. The patient was a man aged 30. In June, 1905, anterior gastro-enterostomy was performed elsewhere for pyloric obstruction. He had had complete relief for four and a half years. Then he had pain in the abdomen to the left of the navel, partly relieved by food. The patient became wasted and for three weeks before perforation the pain was unusually severe. On Sept. 2nd, 1910, at 6.30 P.M., during micturition, suddenly he felt a terrible burning and sharp, aching pain running downwards from the navel to the pubes. The pain was not relieved by morphia. The patient was admitted to Guy's Hospital seven hours after perforation and the abdomen was opened half an hour later. A large amount of sero-purulent sanious fluid and gas escaped. The pelvis, both flanks, and the subdiaphragmatic space on both sides were full of sero-purulent liquid. Anterior gastro-jejunostomy without entero-anastomosis was found; the proximal limb of the jejunum was greatly dilated and hypertrophied. There were dense adhesions between its gastric end and the parietes, indicating old perforation. A large perforation was found in the distal limb 1 inch below the gastro-jejunal opening. The latter was only three-quarters of an inch in diameter. The perforation was closed, the abdomen washed out, and a tube inserted at the lower angle of the wound. The patient did well while in hospital, but soon afterwards symptoms returned in spite of continued medical treatment. He was readmitted once for prolonged medical treatment. He improved a great deal, but had not been out many days before the old pain and vomiting returned. There was burning pain and a feeling of bursting. At the operation in May, 1911, the jejunal ulcer was found adherent to the liver, detached, and thus opened. The pylorus was almost occluded and adherent high up and far back. The jejunum was then detached from the stomach. There was ulceration round the stomach. The jejunal ulcer was excised. The large jejunal wound was closed transversely without narrowing of the lumen. The gastric wound was enlarged up and to the right, and joined to a similar opening made in front of the first and second part of mobilised duodenum. The symptoms had abated. The patient had gained weight, although at work for several months.

Mr. ROWLANDS also showed a case of Gastric Carcinoma; partial gastrectomy two years ago. The patient was a male aged 51. He had had gastric symptoms for four months: vomiting, anorexia, indigestion, constipation, chronic hæmatemesis and melæna, very severe anæmia, and wasting; he had lost 22 lb. in 15 days. An operation was performed in November, 1909, when extensive, but not complete, gastrectomy was done, the duodenum was closed, and gastro-jejunostomy performed. The patient was now quite well and working. At first he could only take small meals; the small remainder of stomach had dilated.

Mr. C. GORDON WATSON showed a case of Excision of a Large Myeloid Sarcoma of the Ischium. The patient was a male aged 51. He had been operated on 12 years ago at St. Mark's Hospital for ischio-rectal abscess. On June 17th, 1911, he was admitted to St. Mark's Hospital complaining of "return of the abscess." On examination there was an elastic swelling bulging into the ischio-rectal fossa, the rectum, and adductor region of the thigh. The tumour was about the size of a cocoanut, was fixed to the pelvis and deep to the thigh muscles, which were wasted. Marked egg-shell crackling was obtained on firm pressure all over the tumour. X ray examination showed that the tumour had a bony shell and was attached to the ischium and pubes. An exploratory incision, followed by microscopic examination, proved the tumour to be a myeloma. On July 7th

he had an operation at the Metropolitan Hospital, when ligature of the internal iliac artery was done. On July 10th the tumour was excised with the patient in the lithotomy position. The greater part of the ramus of the ischium, the tuberosity, and the descending ramus of the pubes were removed with the tumour. The adductors were very adherent to the tumour, and were divided, together with the hamstrings. The sciatic nerve passed over the surface of the tumour, but was not injured. The internal pudic artery was ligatured. A portion of the right crus of the penis was removed. The hæmorrhage was not serious. The tumour was composed of soft vascular tissue, with a thin, bony shell, and consisted of giant cells. The recovery was good; the patient had good use of all his thigh muscles and walked well without pain.

Mr. P. TURNER and Dr. C. E. IREDELL showed two cases of Rodent Ulcer treated by fulguration. The first case was that of a male, aged 56, who was admitted to Guy's Hospital on May 29th, 1910, for a large rodent ulcer which had perforated the right cheek from the anterior border of the masseter to the angle of the mouth, and had also invaded the muco-periosteum of both the superior and the inferior maxillæ. The disease appeared 19 years before in the form of a pimple which did not give rise to any trouble until five years ago, when it began to ulcerate. In 1907 he had X ray treatment under which the ulcer cicatrised. About a year before admission the scar broke down and the ulceration rapidly extended. Radium and X ray treatment were tried for six months, but without benefit. On June 2nd chloroform was administered and the ulcer curetted and scraped, when a large backward extension deep to the masseter and involving the mucous membrane of the cheek was found. When the ulcer had been thoroughly scraped the resulting raw surface was cauterised by the use of the high-frequency current (diathermy). After 10 days a number of superficial sloughs separated, leaving a healthy granulating surface. A sequestrum also separated from the superior maxilla, leaving a large opening into the antrum. The ulcer completely cicatrised in about three months. The obturator for the gap in the cheek was suggested and designed by Mr. F. J. Pearce, assistant dental surgeon to Guy's Hospital. The second case was that of a male, aged 57, who came under observation in 1908. In 1896 the patient noticed a small sore on the left cheek, about half an inch from the ala of the nose. In 1898 it was excised, and recurred two years later. It was then scraped, and later cauterised on several different occasions. In 1902 X ray treatment was started, and he had several hundred treatments. When first seen he had an ulcer about an inch in diameter on the left cheek, equidistant from the left side of the nose, eye, and lip. He was treated with 22½ mg. of radium, having upwards of 50 applications of 36 hours each during the three succeeding years. A piece of lead 1 mm. thick was placed between the radium and the patient. He also had three treatments with carbon-dioxide snow. In October, 1910, the ulcer, which had never healed up, seemed to grow more rapidly, and in January, 1911, he was seen by a surgeon, who suggested removing the whole of the superior maxilla. At that time the lip was becoming involved and also the ala of the nose. The patient refused the operation suggested and was seen again in May. The left upper lip was then destroyed and a good deal of the left side of the nose. The ulceration had also spread on to the left malar bone. The patient was anæsthetised and the edges of the ulcer were cauterised by the method of using high frequency known as diathermy. The right eye being blind, the patient was most anxious that no harm should be done to the left eye, and therefore the part of the ulcer near the inner canthus was left untreated. Since the operation there had been no spread of the ulcer except towards the eye. The patient was shown as an example of treatment by diathermy.

Mr. V. ZACHARY COPE showed a case of Achondroplasia in a male, aged 9, who was about the size of a child of 5. He was intelligent for his age. The stunted growth was noted since he was about 2 years old. All his limbs were much shorter than normal, and the long bones exhibited marked enlargements in the region of the epiphysis, which radiography showed to be due mainly to thickening and irregular ossification of the end of the diaphyses. There were no curves like those of rickets. The fingers and toes were short and thick. The vault of the skull was well developed; the base rather smaller than normal. There was very slight bending of the ribs. The head of the fibula was higher than normal on both sides and took part in the knee-joint on one side. Three brothers and two sisters were well developed. The boy was the youngest child; the mother was aged 41 at his birth. She had a marked enlargement of the right lobe of the thyroid, which had been present as long as she could remember. The case was suggestive of a relation between achondroplasia and derangement of the thyroid.

Mr. W. G. SPENCER showed a case of Congenital Specific Stenosis of the Fauces and Pharynx in a young woman who showed persistent nodes and a gummatous scar on the scalp. In June she was admitted under Mr. Arthur Evans for severe ulceration of the fauces and pharynx. Tracheotomy was done and salvarsan administered, after which the ulceration rapidly healed, resulting in stenosis. Mr. Evans then performed a plastic operation upon the soft palate and fauces; the tracheotomy tube was then left out, and the patient was discharged on August 19th, breathing and swallowing well. On Oct. 15th she was readmitted under Mr. Spencer with dyspnœa, hardly able to swallow fluids. After reintroducing the tracheotomy tube it was found that the naso-pharynx would allow of the passage of only a very small catheter, whilst a No. 10 passed with difficulty through the fauces and pharynx. On gently dilating to admit a finger the fauces and pharynx, down to the larynx, were found to be changed into a very dense ring in which the vessels of the neck had become involved. Therefore a No. 10 œsophageal tube was passed through the left nostril down the pharynx, through which the patient was at first fed, but soon she swallowed beside it. Later, a full-sized œsophageal cannula was passed, beside which the patient could now swallow ordinary hospital diet, and had rapidly put on flesh. She could herself take out the tube when she went out of doors, and put it back before a meal. For the present, therefore, the necessity for gastrostomy had been avoided. The tracheotomy tube would be required permanently. The very dense and extensive fibrosis which had followed the rapid healing of the ulceration after salvarsan was a disappointment.

Mr. V. WARREN LOW showed a case of Multiple Melanotic Sarcomata of the Skin, possibly secondary to a melanotic sarcoma of the skin removed 18 months ago. The patient was a woman, aged 34, who had always had a mole on the inner side of the left leg below the knee. Three years ago this was knocked off and bled and a scab formed. When that either fell off or was removed a raw, bleeding surface remained. Gradually a dark, reddish swelling began to form. The patient was first seen in April, 1910, when the tumour had reached the size of a pigeon's egg. It was pigmented and presented a raw surface covered by a scab. There were also several small, pedunculated, and pigmented tumours attached to the skin on the left thigh. The left femoral glands were enlarged. On April 11th, 1910, the tumour was excised with a wide area of skin around. The femoral glands were also removed and the three pedunculated moles on the left thigh. The material excised was examined microscopically by Mr. E. H. Shaw. The main growth proved to be a melanotic sarcoma; the glands contained secondary deposits similar in character to the growth. The pedunculated tumours showed the ordinary character of simple moles. In January, 1911, the woman again came to the hospital with some small nodules in the scar of the old wound; these were removed and microscopically showed the same characters as the original growth. Shortly afterwards a number of small superficial pigmented tumours began to make their appearance on the left leg below the knee, and this occurrence still continues. At first these made their appearance as small reddish spots in the skin; they rapidly increased in size and became pigmented; they generally projected above the level of the skin, but lately a few small subcutaneous tumours had appeared. During this period the glands in the groin had again enlarged, and now a large mass of glands could be felt in the left iliac fossa extending to the brim of the pelvis. The more superficial glands appeared darkish in colour under the skin. The patient had been treated for three months by X rays by Dr. Robert Knox, who stated in his report that there had not been any improvement. The patient also had some unpigmented moles on the left side of the neck and on the right scapula; a small pedunculated tumour had also appeared on the left thigh in the vicinity of the scars of those removed 18 months ago. The patient, who appeared to be otherwise healthy, was

married and had two children, one of whom had had a large mole removed below the right eye.

Mr. SHAW said that the microscopical sections showed the main growth of the leg (which was soft, pedunculated, white for the most part, with black patches in places, and measured 1¼ in. in diameter) roughly divided into two parts; the outer part was partly covered by an irregular layer of squamous epithelium. The cells of the tumour were arranged in masses separated by connective tissue; they were small and large in size, and very variable in shape, some round and many spindle in outline. All the stages of transition from round to spindle-shape were well seen. Many cells were deeply pigmented, and in some instances whole masses of cells were of a golden brown colour. Many of the pigmented cells were very large, and some contained two or more nuclei. The deeper part of the tumour was composed of smaller cells, mostly round in shape; among these were many well-formed blood-vessels, separated from the cells by a ring of loose connective tissue. The arrangement and character of the cells in the outer part were like those seen in "fleshy" moles, and the tumour undoubtedly arose from one of those. It was now a mixed round and spindle-celled melanotic sarcoma. In the inguinal gland the gland tissue was almost entirely replaced by growth. The growth was composed for the most part of round cells; spindle cells were present in places. Masses of pigmented cells were seen here and there. The tumour was a typical sarcoma. There were two very small moles with wide pedicle. They were covered with squamous epithelium: beneath that there were groups and columns of cells, rounded in shape. Many of the cells contained two nuclei and some contained three or four. The groups were separated by well-formed connective tissue; many cells lay free in the loose tissue just under the epithelium.

Mr. C. A. BALLANCE showed a patient on whom he had successfully performed the operation of Ligaturing the Innominate Artery for Subclavian Aneurysm.

SECTION OF ANÆSTHETICS.

Methyl and Acetone Chloroform.—The Pioneer of Anæsthesia by Ether Inhalation.

A MEETING of this section was held on Dec. 1st.

A letter from the editor of the British Pharmacopœia was read asking for an expression of opinion of the Section of Anæsthetics on the propriety of making methyl chloroform (as well as ethyl chloroform) official in the Pharmacopœia.

Dr. DUDLEY BUXTON said that chloroform prepared from methyl alcohol was, he believed, clinically as good as that obtained from ethylic alcohol. No appreciable difference had been detected throughout a trial, undertaken at his instance, of chloroform made from methyl alcohol and from acetone.

Dr. V. B. ORR said that Westminster Hospital used ethyl $CHCl_3$, but there was no difference detectable between ethyl and methyl $CHCl_3$. He thought a difference could be detected in the case of acetone $CHCl_3$.

Mrs. DICKINSON BERRY suggested that both methyl and acetone $CHCl_3$ should be added as official.

Dr. G. A. H. BARTON said he preferred methyl chloroform; he did not think acetone so good.

Mr. R. GILL said that provided there was purity of production there was no distinction, but that at St. Bartholomew's Hospital they used ethyl $CHCl_3$.

Dr. W. J. MCCARDIE said that as the end produce of manufacture was $CHCl_3$, it did not matter from what source it was obtained. At the Birmingham General Hospital he used methyl and acetone $CHCl_3$ indifferently.

Dr. HERBERT SCHARLIEB said that he had had various brands of chloroform prepared from all sources and he was convinced there was no difference at the time of administration or afterwards.

Mr. R. E. APPERLY thought that more acetone $CHCl_3$ was required to produce anæsthesia than in the case of ethyl or methyl $CHCl_3$.

Mr. H. E. G. BOYLE was convinced that ethyl $CHCl_3$ was less dangerous.

After Mr. GILL had asked whether the question was sufficiently important to be referred to a special general meeting of the section it was decided—

(1) That methyl $CHCl_3$ was sufficiently important to be included in the British Pharmacopœia; and (2) that acetone $CHCl_3$ should also be recommended to be included.

Dr. DUDLEY BUXTON read a paper the subject of which was Crawford Williamson Long, the Pioneer of Anæsthesia by Ether Inhalation: the Use of Ether 1842 and 1911. He pointed out that Long sprang from a family of strong intellectual bias, was himself at once an exceptionally able man, imbued with professional horror of advertisement and of premature exploitation of hastily carried out professional research. At the time of his first experiences with ether inhalation (1841) that drug was unknown except as an exhilarant, for which purpose it had been employed by Beddoes, Pearson, Warren, Cullen, and others. In this way it was employed by Long instead of nitrous oxide gas, the inhalation of which was a common pastime among the youth of England and the United States. Long, observing that the pain of bruises and bangs was not felt after breathing ether, was led to employ it to produce full surgical anæsthesia. This he did in 1842. Subsequent successes led to remonstrances from neighbouring medical men, who feared a disaster, since Pereira and others had taught that the stupor of ether was highly dangerous. Since Long practised in a small village out of touch with surgical centres, he refrained from publishing his work, although it was known throughout the State of Georgia. When Morton sought to obtain sole credit from Congress and a pecuniary reward for his public exhibition of his nostrum letheon, which was in fact sulphuric ether, Long was pursuaded by his friends to send a succinct account of his cases which had been done four and a half years earlier. He refused to court further recognition, and for many years Long's name was seldom associated with the great discovery of anæsthesia. Dr. Buxton's paper was illustrated by a series of interesting photographs of the original documents proving the justice of Long's claims to be accepted as the first person to suggest the use of ether for anæsthesia and the first person actually to employ it. Besides tracing Crawford Long's career, a full account based on the protocols was presented of the actual work done and the state of medical thought concerning mesmerism and other attempts at the achievement of painless surgery. The methods of using ether between 1841 and 1911 were considered and comparisons instituted, a final appeal being made that those who practised anæsthesia should supplement their practical skill by research so that the art should follow the extension of the science.

LARYNGOLOGICAL SECTION.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Dec. 1st, Dr. STCLAIR THOMSON, the President, being in the chair.

Mr. J. EVERIDGE (introduced by the PRESIDENT) showed a Pedunculated Intrinsic Growth of the Larynx in a man aged 41. The case was shown at the last meeting. The growth had been removed, and the section under the microscope showed that it was a granuloma.

Dr. W. JOBSON HORNE showed a series of three cases of Specific Disease of the Tongue, Palate, and Fauces, one of the cases manifesting fenestræ the result of the disease in the posterior pillars of the fauces.

Dr. G. WILLIAM HILL showed a patient with Fixation of the Left Vocal Cord and Tracheal Tugging from Aortic Aneurysm, which gave rise to an interesting discussion initiated by Mr. W. PERMEWAN (Liverpool), who expressed the opinion that undiagnosed cases of recurrent paralysis of the left vocal cord would be more frequently found to be due to aneurysm than to any other cause—an opinion which was not, however, allowed to pass unchallenged.

Dr. HILL also showed some Pieces of a Chestnut he had removed with the aid of upper bronchoscopy from an infant 13 months old. The case was one of the youngest on record.—Several members advised lower bronchoscopy at such early ages in order to avoid the glottic œdema which is liable to follow the passage of the tube through the infantile glottis.

Dr. W. H. KELSON showed a case of Tuberculous Disease of the Larynx in a man, aged 37, to illustrate the fact that in tuberculous disease the larynx did not heal *pari passu* with the lung.

Dr. KELSON also exhibited a case of Abductor Paresis in a man, aged 44, with tuberculous disease of both apices, regarding which several members expressed dubiety as to the presence of any abductor disability.

Dr. DAN MCKENZIE showed a woman, aged 57 years, who had suffered from Prolonged Laryngeal Stenosis from some obscure inflammatory cause (? pneumococcus infection). The

practical interest in the case lay in the fact that in the early stages sarcoma of the pharynx had been closely simulated.

Dr. MCKENZIE also showed another Laryngeal Case of Doubtful Diagnosis.—This was considered by most of the speakers to be an example of simple pachydermia.

Mr. HERBERT TILLEY showed a large Suppurating Bony-walled Air Cell of the Right Middle Turbinal which had been associated with chronic empyema of the corresponding antrum.

Mr. TILLEY also showed an old man in whom an External Fistula of the Frontal Sinus had been cured by intra-nasal treatment.

Mr. GEORGE WILKINSON (Sheffield) exhibited a case of Unilateral Paralysis Affecting the Face, Pharynx, Larynx, and Tongue, acute in onset and diagnosed as due to acute polio-encephalitis.—The danger to the ear in bathing is well known, although it is not so frequently guarded against as it ought to be, but that the nasal sinuses may become infected in the same way has hitherto escaped notice. Mr. Wilkinson, however, in his notes of three cases illustrating Infection of the Accessory Sinuses by Entry of Water into the Nose during Bathing, and of a fourth case having possibly the same origin, drew attention to a point in etiology of which more would doubtless be heard.

Mr. WILKINSON also reported a case of Osteomyelitis from Acute Frontal Sinusitis.

Mr. E. W. BAIN exhibited a Papilloma growing from the Inferior Turbinal, a specimen which was not, however, considered to be an example of this uncommon type.—A discussion upon the rare squamous papilloma of the nose followed.

Dr. T. JEFFERSON FAULDER and Mr. W. H. HARMER showed a case of Pharyngeal Tuberculosis, with tuberculous lesions of other parts, which was under treatment by injections of tuberculin. The appearances of the pharyngeal ulcers were so unusual as to arouse considerable comment. It appeared that the tuberculous disease had spread from the tonsils to the pharyngeal wall after simple tonsillotomy some years ago, an event which many of the members regarded as strengthening the case in favour of entirely enucleating tonsils; and the same opinion was expressed in the discussion on a case shown by Dr. E. A. PETERS of an Irregular Growth from the Tonsil which had appeared in spite of an operation upon the tonsils seven years previously.

Dr. HILL showed two cases of Carcinoma of the Deep Pharynx prior to their treatment with radium.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

Sterilisation from the Eugenic Standpoint.

A QUARTERLY meeting of this association was held at the rooms of the Medical Society of London on Nov. 21st, Dr. WILLIAM DAWSON, the President, being in the chair.

Before proceeding to the business of the day, the PRESIDENT referred in sympathetic terms to the decease since the last meeting of Dr. George Fielding Blandford, who was one of the oldest members of the association and a familiar figure at most of its meetings, where everyone listened with the greatest respect to his remarks. Dr. Blandford was a past President of the association, and had always taken a deep interest in lunacy legislation. The funeral was attended by some members of the association and a wreath was sent. He proposed that a vote of condolence be forwarded to the relatives This was carried in silence by the members rising. He also referred to the death of Dr. James Murray Lindsay, another very old member, who had also been President of the association. During his presidency a very successful meeting was held at Buxton 18 years ago. Dr. Lindsay took a great interest in the pension question. A proposition that a letter of condolence be sent to the relatives of Dr. Lindsay was carried in the same sympathetic manner as was the former vote.

A very interesting paper was read by Dr. GEOFFREY CLARKE on Sterilisation from the Eugenic Standpoint. The paper was largely based upon a laborious investigation and analysis of the cases in the Long-Grove Asylum, Epsom. Dr. Clarke passed in review the recent discussions which had taken place concerning the elimination of what were called the unfit members of the community and the measures by which it was proposed to carry this out. The advocates of sterilisation averred that present-day medical and hygienic care resulted in keeping alive a greater proportion of weaklings than formerly; but it must be remembered that there were many others whose early years were full of ailments and a source of anxiety to their parents, but who yet blossomed into vigorous and healthy adults. The great question which required answering was, Had the advances in science tended to impair the mental and physical qualities of the race? He contended that the arguments and conclusions of stock-breeders could not be applied to human beings; the mental as well as the physical had to be reckoned with, and he did not think knowledge had yet advanced sufficiently far to enable anyone to say to certain people that they must not be permitted to reproduce their kind. Insanity was not a definite disease, but a variation from the average normal standard, the standard itself varying with the country and time, and even in different places in the same country—i.e., a person might not be able to stand the stress and surroundings of a London slum, but could live a successful life in a quiet country place. Moreover, there was a large class of mental degenerates who were yet not insane. If sterilisation were to be adopted it should take place in some forms of mental disease quite apart from the eugenic standpoint. He thought it had yet to be shown that any practicable scheme of sterilisation would materially diminish the normal rate of increase of insanity. He did not think that any hope of a material decrease of insanity was justified on the statistics at present available. There was great need of a better record of family histories which should be kept quite separate from the present statistics that had to be furnished, and which he regarded as useless for such an inquiry as the present one. At present the defective histories swamped the good ones. What was needed was full information, even if only a few families were taken, giving the normal as well as the abnormal.

The PRESIDENT congratulated Dr. Clarke on his paper, which was an attempt to place upon reasonable, scientific, and arguable lines the statements that had been made with regard to inheritance of insanity. At present there was much loose talk on the subject, and that made reliable statistics all the more necessary.

Dr. T. E. K. STANSFIELD, who had read a paper on a kindred subject at a recent meeting of the South-Eastern division of the association, said that all who had to do with asylum work would feel that something ought to be done to stem the flow of the insane and the unfit. Some years ago he suggested to the London Asylum Committee that there should be a special officer appointed whose function should be to go to the homes of these people, see the relatives, and estimate the amount of insanity, of course uncertified, present among them. He still hoped that something of the kind would be done.

Dr. M. EDEN PAUL agreed that there was not yet sufficient knowledge nor enough detail in family histories to enable one to say how much insanity was the direct result of inheritance. But he thought efforts should not be delayed simply because the information desired was not available in its entirety. The public was now happily awakening to the importance of trying to do something to improve human stock, and the public looked to members of the association for guidance in the matter. He did not agree that the experience of breeders of animals was not of much use in regard to human beings; it was the average which it was desired to raise, and that was also one of the aims of breeders; it was not always to raise highly specialised types. Sterilisation did not appear so necessary in the case of those who were definitely insane as for those whose mental capacity prevented certification but who were free to propagate their species, such as the feeble-minded. There seemed to be a case made out for small beginnings and for trying to guide public opinion on the matter.

Mr. H. WOLESLEY LEWIS, while agreeing that the material available did not justify sterilisation, thought that the mere fact that 50 per cent. of persons admitted into asylums had a hereditary nervous history made out a strong case for segregation, even permanent, and that might be extended to the habitual criminal and the inebriate class, as they both suffered from very defective self-control.

Dr. A. N. BOYCOTT regarded sterilisation as an impracticable policy, and thought it would remain so for some hundreds of years; moreover, no Government would listen to

such an idea. He did not express any opinion as to its merits in the abstract. He pointed out that statistics which lumped all forms of insanity together were of no use for such an inquiry as this.

Dr. M. A. COLLINS, referring to the statement regarding the increase of insanity, pointed out the more thorough system of certification, which included the kind of person who was formerly regarded as the harmless village idiot; and reminded the meeting of the increasing stress of life and the continual elevation of standards of education and equipment and also of the falling birth-rate.

Dr. C. HUBERT BOND thanked Dr. Clarke for his paper and for the time which he bestowed on analysing the Long-Grove statistics, which were very full, as he (Dr. Bond) made a point of trying, in every case admitted into Long-Grove, to ascertain from the superintendent of any previous asylum the patient had been in particulars of the case and also particulars concerning any relatives said to have been insane. In that way a multitude of information had accumulated there. He reminded the meeting of the falling birth-rate, in view of which the suggestion as to sterilisation was a very serious one; particularly was extreme caution necessary as proofs were not yet forthcoming. It seemed worthy the care of a special committee. Sterilisation might open the door to many very grave abuses.

Dr. D. G. THOMSON regarded such schemes as futile. Certainly sterilisation should not be one of the horrors of certification, because it would defeat its own ends, even if it were desirable. If people knew what it meant they would seek to still further evade certification than at present. Shortly, the medical inspection of school children would enable them to know more on the subject than at present; to wait until such knowledge was available would be far better than any attempt at tinkering with the subject.

Dr. J. G. SOUTAR said the question of heredity in mental conditions was one of the most difficult which met the physician day by day. People seemed to vary enormously in regard to heredity. There were stocks amongst one's patients so bad that they produced little but neurotic and insane progeny. Yet, notwithstanding that, there were an enormous number of highly competent men and women who had been doing the most important work of the world. That was a fact which should weigh with those who considered tables of heredity. He supported the idea of personal histories being taken much more carefully and thoroughly than at present, then one could get much nearer the truth than was possible now. One value of the paper was that it revealed a lack in the profession of adequate knowledge on the subject. The slums of the large cities of the empire were factories for the production of feeble-minded persons—their surroundings, their wages, the poor food they had, the bad clothes, the abominable houses, all constituted factors in that direction. Mothers in such conditions bringing forth children became more feeble with each birth, and starvation was the lot of the child. Something more might be done than at present to improve environment, for in that direction lay much hope for stemming the tide of mental disease.

Mr. H. F. HAYES NEWINGTON reminded the meeting that the union of sanity and insanity did not necessarily produce bad results in children, and that he regarded as an indication that Dame Nature, in her wisdom, was working to restore the normal. The main trend was not for such union to bring sanity down to the level of insanity but to approximate insanity nearer to sanity. He deprecated any attempt to interfere with the laws of reproduction; there were channels of improvement open short of sterilisation.

Mr. G. M. ROBERTSON said the whole problem rested largely on the question of heredity. He agreed that nature stepped in and did more than men's schemes were ever likely to do in an artificial way to check the production of the unfit. The largest number of cases of hereditary insanity occurred at an early age, and therefore in those who did not procreate. The general trend of disease was towards recovery, towards the normal. More good would be done by encouraging the marriage of physiologically healthy people. Sterilisation had only once been suggested to him. He quite agreed with what had been said about the more thorough record of family histories.

Dr. CLARKE replied, reminding the meeting of his chief point—namely, that sufficient information was not available on the mental side of heredity.

JOINT MEETING WITH THE GYNÆCOLOGICAL AND OBSTETRICAL SECTION OF THE ROYAL SOCIETY OF MEDICINE.

Amenorrhœal Insanity.

The association, at the close of the quarterly meeting recorded above, went into a joint session with the Section of Gynæcology and Obstetrics of the Royal Society of Medicine, Dr. AMAND J. M. ROUTH, the President of the section, being asked to take the chair.

Dr. C. T. EWART, in introducing for debate the subject of Amenorrhœal Insanity, dilated on the fact that menstruation was a rhythmical periodic function, that amenorrhœa was produced by the internal secretion of the ovaries, and he asked the question whether in insanity associated with the suspension of the menses the latter was a cause or an effect. He considered that there was a form of insanity due to suppression of the menstrual flow, and where that was the case the patients recovered in three months from the re-establishment of the menstruation. In every such case there was a heredity which caused the patient to have an unstable nervous system. Whatever toxic substance was contained in the menses was in such a case thrown into the general circulation, and such patients were peculiarly susceptible to toxic influences. He regarded good environment as the main factor in recovery. The paper led to a very interesting discussion.

Dr. ROBERT JONES (London County Asylum, Claybury) paid a high tribute to the author of the paper. He regarded the reproductive function as the highest function. Animals in captivity, such as at the Zoological Gardens, had good general health, but they suffered in the reproductive function. Presumably the nervous system was at fault. It was well known that the advent of menstruation was attended by definite and distinct psychical conditions, probably due to internal chemistry. Dr. Ewart found that heredity was responsible for 83 per cent. of the cases. Animals propagated their species in special seasons, the only exception being man. In regard to women, the two points which came out were periodicity and their liability to be affected by environment. The growth of plants could be greatly changed by modifying their environment, and he remarked that in 1824 Jenner pointed out, in the Philosophical Transactions, that the migration of birds was accompanied by a fleshy condition and increased size of their ovaries. Others had described atrophy of the ovary of the cuckoo in the month of July. He considered that the asylum was the best place in which to study those refined and subtle changes in the mental conditions due to forms of peripheral stimulation. The neurasthenic and the psychasthenic were splendid weather glasses. A large number of anæmic girls entered Claybury Asylum suffering from amenorrhœa, and in many when the menses were re-established mental recovery took place. Towards this Turkish baths and other means of eliminating toxins were of great value. The climacteric was also a very important period. A great deal of loose talk was indulged in on this subject, but everyone would admit that in all women menstruation imposed a considerable strain, while in those with an ill-balanced nervous system it was a dangerous period.

Dr. H. MACNAUGHTON JONES remarked that we had now much more accurate knowledge on the subject of menstruation, ovulation, and the relation of the latter to the metabolism of the ovary and to the general metabolism of the body, but particularly that of the uterus, both pregnant and non-pregnant; also as to the psychical effects of the ovarian secretion. With regard to the term "amenorrhœal insanity," there was nothing more dangerous than to introduce a term which was not strictly accurate. He did not see why a woman or girl who was psychasthenic or neurasthenic, and who also had stoppage of the flow, should be classed as a case of amenorrhœal insanity. He believed most cases of insanity had their hearts affected, but one would not suggest on that account that the people had cardiac insanity. He did not think the term under discussion was justified.

Dr. R. PERCY SMITH expressed his pleasure at hearing Dr. Macnaughton Jones's point of view. There might be amenorrhœa both in cases of melancholia and in cases of mania and insanity was often associated with amenorrhœa, but he did not think there was a special amenorrhœal insanity. It must be remembered that amenorrhœa was a very common symptom in all acute insanities in women. If the term was justifiable in any cases it was in those young women

in whom there had been prolonged fatigue or stress due to exhausting occupations, leading to great anæmia. If amenorrhœal insanity was a definite disease, it should be diagnosable early, not from the fact of recovery three months after the return of the menses.

Dr. RUSSELL (Glasgow) agreed with the criticism of the term which had been offered. In his experience amenorrhœa in cases which had nervous disturbance he regarded as the effect rather than the cause. He described one case in which mental trouble occurred simultaneously with a growth of the ovary, and when that was removed the normal mentality returned. Among young women of this class one could trace persistent neglect of the proper principles of feeding, and, very important indeed, regular relief of the bowel.

Dr. DAWSON (Dublin), President of the Medico-Psychological Association, found himself in agreement with the three last speakers. He did not believe there was a special form of insanity caused by amenorrhœa. The form of insanity most commonly associated with amenorrhœa was melancholia, and those subjects were most apt to have disorders of digestion, sometimes associated with diseased kidneys. Of course, he agreed that amenorrhœa affected the mental condition of the woman, even many sane women. Anæmic girls were particularly liable to nerve symptoms at menstruation.

Dr. WALTER S. A. GRIFFITH said that it was not very clear what was meant by amenorrhœa. The condition was not merely the loss of blood and mucus; that was a mere phenomenon in it. It would have been better if Dr. Ewart had defined exactly what was meant. He agreed with Dr. Percy Smith that the gynæcologist had no definite place in the asylum, and that the insane woman should not be touched in this respect unless an operation was required, such as for a growth. If a robust healthy girl did not menstruate for years there was something definite which neither iron, nor purgatives, nor exercise, nor fresh air would do good to.

Mr. HAYDN BROWN strongly advocated a greater use in the profession of psycho-therapy for nervous conditions.

Dr. W. H. B. STODDART associated himself with most of the speakers in denying that there was such a disease as amenorrhœal insanity. He regarded the amenorrhœa as simply a concomitant symptom. He, however, gave an instance of a woman upon whom he carried out a process of psycho-analysis, which was followed by a return of the menses, and from that time she improved mentally.

Dr. AMAND ROUTH congratulated the joint meeting on the discussion. It was known that menstruation was due to something, some chemical agent, which accumulated in the blood, and ultimately reached a certain pitch and encouraged the uterus and the ovaries to become active. The change in the blood was due to the formation of an excess of calcium, and the first act of the menstruating uterus was to excrete a large quantity of lime salts which lowered the lime content of the blood and encouraged hæmorrhage from the uterus. Amenorrhœa showed that the products which ought to be in the blood in order to encourage menstruation were absent. So probably amenorrhœa meant the patient suffered from a diminution of some substances and an excess of others.

Dr. EWART replied, but did not attempt to traverse all the arguments which had been adduced owing to the pressure of time.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 21st. Dr. S. Lodge, the President, being in the chair.—Dr. F. W. Eurich read a paper on Some Interesting Cases of Typhoid Fever. He said that diagnosis was often difficult at the beginning of a straightforward case, but it was infinitely more difficult in the absence of the usual signs and symptoms, several cases of which had recently come to his notice. Afebrile cases were especially difficult. He instanced one in which the gastro-intestinal symptoms had predominated, and in which a swinging temperature developed only when the diagnosis had been made on other grounds. In a second case a woman in failing health became suddenly comatose, with cyanosis and coldness. In her the nervous symptoms had predominated, and the absence of fever had increased the difficulty of arriving at the cause. The symptoms of a third patient began with neuritis; she rapidly developed a "typhoid state" and died. Even when fever occurred diagnosis was not always easy. A fatal attack began in the case of a man with a conjunction of the symptoms of appendicitis with those of dilated stomach. The occurrence of hæmatemesis did not help to clear the matter up, and a Widal test, which proved strongly positive, was done only because the patient's general state resembled typhoid fever. The complications of typhoid fever might occasionally be the first sign of the disease. A case illustrating this was described. The value of the Widal test was insisted upon. It was not positive before the eighth day, and might not become so until after convalescence. On the other hand, it remained so for months and even years. Hence with a positive Widal a previous attack must be excluded. Repeated examination was advisable, since both the development and the increase in intensity of an already positive Widal indicated an attack. A leucocyte examination was often helpful in addition, for marked leucocytosis or the presence of the alterations diagnostic of other conditions might exclude typhoid fever. Of course, suppuration accompanying enteric fever would cause leucocytosis.—The paper was discussed by the President, Dr. R. A. R. Lankester, Dr. A. F. Martin, Dr. J. Metcalfe, Dr. J. B. Lockerbie, Mr. F. W. Goyder, and Dr. W. Ward-Smith.—Dr. H. J. Campbell spoke of the variations in children, recurrent typhoid fever, and treatment.—Dr. Eurich replied briefly.—Dr. A. C. F. Rabagliati gave a short paper on Some Common Fallacies of Medical Logic. He said that medical men were usually fairly reliable as to the facts of a case, but that their deductions were by no means always the logical inference of their observations. Two fallacies were common. Because, for instance, two symptoms were constantly found together, it was not logical to elevate one to the position of being the cause of the other. Both might be due to a common cause. Again, because a certain disease appeared in a particular family at the same age, it did not therefore follow that the disease was hereditary. It was to some extent an assumption that the previous condition was the cause of the subsequent one. Neither did it follow that the recurrence of the same or even of different diseases in the same individual was the cause of any subsequent condition. All might be due to a common and wholly different cause. Various instances of these fallacies were given, and Dr. Rabagliati argued that real progress as to the causation and the treatment of disease could not be made unless accurate deductions and accurate facts were regarded as of equal importance.—The paper was discussed by the President and Mr. Goyder, and Dr. Rabagliati replied.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 6th, Dr. F. H. Jacob, the President, being in the chair.—In opening a discussion on "Alcohol as a Drug," Dr. C. H. Cattle pointed out how custom had changed during the last 30 years with regard to the administration of alcohol in disease. When he started practising, alcohol was always given to consumptives; now the modern treatment of consumption was to increase the patient's resisting power, whereas modern science taught them that alcohol lowered the resistance. Surgeons now seldom used alcohol to combat traumatic shock. Enormous doses used to be given in cases of puerperal fever, but now it was seldom ordered. The records of the asylums of London showed some striking figures: in 1889, 1900 gallons of wine and spirits were consumed by patients; in 1905 only 250 gallons were used. Considering the fact that the number of patients was doubled during that period, it meant that only one-sixteenth the amount of alcohol was used in the latter period. The records of all the London hospitals showed the same result. No definite dose of alcohol is advised; he himself generally ordered when he did employ it in small doses, such as half an ounce every four hours. After referring to the physiological action of alcohol Dr. Cattle considered the circumstances in which alcohol should be used. They must remember that the patient had unlimited access to the drug, and therefore it should never be employed in cases of neurasthenia or dyspepsia. In severe febrile cases such as typhoid fever or pneumonia, where the pulse was failing, alcohol might be given in small doses, also in the first stage of threatened delirium tremens.—The President stated that he had found alcohol in large doses useful in cases of extreme collapse; he had also seen much improvement follow its use in cases of phthisis and eczema. However, he seldom especially ordered it except in cases where the temperature was very low and the pulse was small, then he found it useful as a temporary stimulant.—Dr. Sarah

Gray said that although personally a teetotaler she nevertheless found alcohol useful in stimulating the appetites of patients after long and severe illnesses. It was extremely dangerous to give it at the menopause or to neurasthenics.—Dr. A. Fulton pointed out the danger of giving it in cases of dysmenorrhœa or as a galactagogue.—Mr. J. Watson said that medical men seldom ordered alcohol—the patients themselves took it, and it was for the medical man to prohibit it or not, as he thought fit. He employed saline injections to combat shock. Alcohol in the form of champagne was useful in cases of post-anæsthetic vomiting.—Dr. T. D. Pryce thought they knew very little about the action of alcohol, and thought the disuse of alcohol was largely the result of fashion. He found that it stimulated the gastric secretion in cases of long illnesses such as typhoid fever, and it was very useful as a temporary stimulant.—Mr. A. R. Tweedie mentioned that in the late war small doses of alcohol were given to the men after forced marches to enable them to take their rations better.—Dr. M. Parry-Jones (Derby) was quite convinced of its value in urgent cases. The great opposition to alcohol was largely carried on by specialists, who did not have the practical experience of daily seeing urgent cases right through to convalescence. The vintage ordered was more important than the quantity.—Mr. R. Nesbitt, Dr. J. S. Bolton, and Dr. F. R. Mutch continued the discussion.

OXFORD MEDICAL SOCIETY.—A meeting of this society was held in the Radcliffe Infirmary on Dec. 8th, Dr. W. Arthur Waters, Vice-president, being in the chair.—Mr. A. G. Vernon Harcourt gave a demonstration of a safe method of the administration of chloroform. He emphasised the importance of concentration as being the most essential feature to control. The instrument shown was designed to give varying percentages of chloroform, but a maximum 2 per cent. was sufficient for full anæsthesia in the hardest drinker. The details of the apparatus were explained, and the special points designed to overcome various defects, especially the varying temperature of the liquid chloroform in the receptacle bottle. A modification was shown by which air or oxygen could be supplied under a slight pressure. Deaths under chloroform by the use of this apparatus were preventable and post-anæsthetic sickness was greatly diminished.—Dr. W. Collier emphasised the dangers of chloroform even in the most skilled hands under the old method.—Mr. A. P. Dodds-Parker read a paper on the Fate of the Appendix after Abscess Formation. He said that he had been able to collect during the previous six years 17 cases, which he had tabulated, showing the history subsequent to abscess formation and the state of the appendix at the operation. Some of the specimens were shown. The conclusions drawn from this inquiry were: (1) The appendix was never destroyed, but was damaged; (2) there was liability to fresh attacks with such a diseased organ in the belly; (3) in the present keen struggle for existence it was wiser to remove such a menace to life; (4) the danger of a second operation was not great and herniæ might at the same time be cured. The mortality in the 17 cases recorded was *nil*.—In the discussion which followed Dr. Collier bore out Mr. Dodds-Parker's conclusions, emphasising the fact that appendicitis was now much more deadly than formerly. He also mentioned the good effects of fibrolysin in reducing the bulk of the adhesions in a case known to him.—Mr. E. Cecil Bevers mentioned that early operation had now resulted in the abscess formation being very rare; he also thought that it was justifiable to attempt to remove the appendix in many cases at the same time that the abscess was evacuated. He mentioned a case in which no appendix had been found in an operation subsequent to the evacuation of an abscess.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 7th, Mr. T. H. Ionides, the President, being in the chair.—Mr. G. Morgan showed a baby of a few months of age with a Lipoma in each cheek.—Dr. Walter Broadbent exhibited a woman, aged 54, with a large Aneurysm of the third part of the arch of the aorta. She had a paralysed left vocal cord, tracheal tugging, and unequal pupils. There was dulness in the first, second, and third left spaces for about three inches from the edge of the sternum, and pulsation could be felt. The second sound was loud over this area, and the breath sounds were tracheal in character over the upper lobe of the lung. There was no history of syphilis, but she had done heavy lifting. The chief point of interest was that she had been under treatment for two years, and the aneurysm had become smaller and the pulsation less. This was very uncommon when the second or third part of the aorta was affected.—The President showed two Uteri, one with a very small fibroid, but which had given rise to severe hæmorrhage for nine months, and the other in an early stage of sloughing.—Mr. H. Nethersole Fletcher showed a Kidney removed for calculi. There was a 30 years history, during which the patient had passed 324 small stones. In the kidney removed there were some hundreds of minute stones, and one large branched one.—Dr. Herbert French read a paper entitled "High Blood Pressure and the Commoner Affections of Arteries."

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on Dec. 8th, Dr. A. Bostock Hill, the President, being in the chair.—In introducing a discussion upon the Notification of Births Act, 1907, Dr. A. A. Mussen stated that while 148 of the 250 metropolitan boroughs, county boroughs, and non-county boroughs had adopted the Act, exactly the same number among the 1500 urban and rural districts had adopted it. In Liverpool 84 per cent. of the total number of births were notified—60 per cent. by midwives, nearly 10 per cent. by medical men and over 10 per cent. by institutions. He did not regard the small number of notifications by medical practitioners with much concern, for notifications were received from other quarters of all the births concerning which administrative action could be taken. Regarding prosecutions under the Act in Liverpool, the health committee in a few cases instituted proceedings against uncertified women for not having notified births that had occurred under their care. In one or two cases a fine of 5*s*. was inflicted; in others the defendants were dealt with under the Midwives Act. The Act was very useful in assisting in the discovery of neglected cases of ophthalmia neonatorum, not of acute cases, but of those where the child had had slight conjunctivitis which had been treated by the mother or midwife and was getting into a chronic inflammatory condition which in time would cause opacity in the cornea. He was convinced that the Act was a valuable piece of legislation for directing the efforts of a sanitary authority, more especially of those having under their care a large poor-class population living under conditions detrimental to infant life. It gave the health department one of the best chances of teaching the rudiments of health in the homes of the poor at a time when they were exceptionally susceptible to such teaching.

ASSOCIATION OF CERTIFYING FACTORY SURGEONS (INCORPORATED).—The annual dinner of this association was held in London on Dec. 8th at the Trocadero Restaurant under the chairmanship of the President, Mr. W. F. Dearden (Manchester). The dinner was well attended and a very enjoyable evening was spent. A letter of regret and good wishes was read by the chairman from Mr. C. F. G. Masterman, M.P., who, like Sir Thomas Oliver, was unable to be present. After the loyal toasts had been honoured, Dr. R. W. Edginton (Birmingham) proposed "The Home Department of His Majesty's Government." He spoke in particular of the branch which came into close touch with the work of the association, and expressed the thanks of the members to the heads of the department for their courtesy and interest. Sir Arthur Whitelegge, in reply to the toast, insisted upon the importance of standardising certificates, a process unfairly described by philistines as "red tape." He indicated some of the past and future activities of the officers of the department in fighting industrial disease, and referred to valuable recent researches into the questions of dust and humidity, of the methods of illumination, and of fatigue. Dr. T. M. Legge, in proposing the toast of the association, spoke of the dependence of the department upon the coöperation of the certifying factory surgeons, and pointed to the steady decline in industrial disease mortality which had occurred in recent years. The chairman replied and thanked Dr. Legge on behalf of the members for his individual interest in their work. The health of the guests was submitted in a breezy speech by Dr. J. H. Keay (Greenwich) and was responded to by Mr. R. J. N. Neville, M.P., and Dr. T. D. Lister, who rounded off the evening with some amusing "digressions."

Reviews and Notices of Books.

Reproduction in the Human Female: The Uterine Mucosa in the Resting, Menstrual, and Pregnant States, and the Function of the Decidua. By JAMES YOUNG, M.D. Edin., F.R.C.S. Edin. London and Edinburgh: William Green and Sons. 1911. Pp. 222 and 68 Plates. Price 21*s*.

THE scope of this work is better indicated by the subtitle than by the title, as it deals chiefly with the structure of the uterine mucous membrane and the changes that it undergoes during menstruation and pregnancy. This is only a small portion of the large problem of reproduction in the human female. It is, however, a very important part, and whatever we may think of the author's conclusions, there can be no question as to the great value of his researches and of the very suggestive nature of the work that he has done.

He regards the uterine mucosa as a soft, semi-fluid, protoplasmic mass, imperfectly differentiated into cellular elements, in which the intercellular spaces in all probability do not communicate with one another. The walls of the vessels are nothing more than flattened stroma cells, and except in the deepest layer of the mucosa they have no specialised supporting coats. The œdematous changes in the tissues which precede the escape of the blood in menstruation Dr. Young believes to be due to protoplasmic changes resulting in an active imbibition of fluid from the vessels. This conversion is brought about by the liberation in the tissues of crystalloidal or colloidal elements with an increased affinity for fluid. These tissue changes are due to some material (secretion or hormone) liberated by the ovary and reaching the protoplasm of the mucosa *viâ* the blood-vessels. In the pregnant tube, what the author calls the extra-chorionic influence of the fœtal cells—that is, the extraneous changes induced by the chorion in the maternal tissues—leads to marked degenerative changes. The extensive œdema and hæmorrhage which occur in the tubal wall are assumed to be due to the same causes as are operative in the uterus—namely, the production or liberation of crystalloids and an increase in the affinity of the tissues for fluid. The resulting splitting up and solution of the tissues explain the manner in which the implantation chamber is formed, and also the way in which many of the blood-vessels invade the maternal tissues to form large blood-tracks. In cases of chorion-epithelioma which the author has investigated the same conditions are found. The chorionic influence in some way or other determines the occurrence of protoplasmic changes in the cells, which lead to their imbibing fluid that can often be seen to have accumulated in the cell body under a hydrostatic pressure clearly higher than the pressure of the intravascular blood, and of the fluid in the surrounding tissue spaces. This, no doubt, must be explained in the same way by the occurrence of some chemical substance in the cell substance which is associated with the liberation of elements with a greater affinity for fluid. These changes are responsible for the marked œdematous infiltration and escape of blood from the vessels that are so characteristic of chorion-epithelioma.

Dr. Young describes a young ovum which he had the opportunity of examining and which he estimates to be of about the age of 13½ to 14½ days, or midway between the Teacher-Bryce ovum and that of Peters. The chief points of interest presented by this early ovum are that the blastocyst is completely filled with mesenchyme and is much smaller than the implantation chamber, while the decidual development is less evident than in any other young ovum. As a result of his investigations on the decidual changes in the uterus and the pregnant tube the author puts forward an ingenious theory as to the functions of the decidua. He suggests that its function is to prevent an irregular and increasing opening-up and expansion of the maternal vessels and a tearing-up of the mucosa by fluid and blood, after the tissue changes necessary for an adequate supply of the maternal blood for the engrafted ovum have been accomplished. It is by virtue of this action that the chorionic invasion of the tissues is limited and that the increase in the implantation chamber by an erosion or displacement of tissue is prevented.

The final chapter is devoted to a consideration of the various theories of the causation of œdema. Dr. Young says that his investigations—the first attempt to explain the mode of production of œdema by a histological survey of the tissue changes—have demonstrated that the fluid escapes from the vessels, not in response to a mechanical filtration, but in consequence of an alteration in the tissue protoplasm which determines an imbibition of the blood fluid.

The interpretation placed by the author upon the appearances he describes—which are illustrated by a beautiful series of 68 plates—is a very plausible one, and the book represents the outcome of a large amount of work and has much merit.

Untersuchungen über die Struktur der Blutzellen. Von Dr. ALFRED V. DESCATELLO und Dr. A. KRJUKOFF (Moskau), der Medizinischen Klinik in Innsbruck. Mit 8 chromolithographischen Tafeln. Berlin und Wien: Urban und Schwarzenberg. 1911. Pp. 119. Price, paper, 16 marks; bound, 18 marks.

Technik der Klinischen Blutuntersuchungen für Studierende und Aerzte. Von Dr. A. PAPPENHEIM, Berlin. Berlin: Julius Springer. 1911. Pp. 55. Price, paper, 2 marks; bound, 2.60 marks.
